THE location of the load center of a circuit with a distributed load must be determined before any wiring formula can be correctly used for it. The load center of a circuit is that point at which the total load on the circuit can be assumed to be concentrated when making wiring calculations. An electrical-load center is somewhat analogous to a center of gravity of a body. To illustrate, in Fig. 1 all of the eight lamps are of the same size and equal distances apart. The load center for the branch circuit lying between switch S and the last lamp B is at AA; that is, it is at the middle of the group of lamps. The distance from the starting point S of the circuit to the load center, denoted by D, would be used for the distance D in the direct-current formula, cir.mils. $= \frac{22ID}{E_d}$. The voltage drop E_d in the formula would be the drop in the circuit from the switch S to the last lamp B. The current I of the formula would be the total current taken by all of the eight lamps, or for any condition the sum of the amperes taken by all the elements on the circuits. If the conductors were calculated for a drop of 5 volts, the drop between S and B would be 5 volts. Then if the electromotive force impressed at S is 110 volts, the pressure at lamp B, with all lamps burning, will be 110 — 5 = 105 volts. The other seven lamps in the group would be subjected to somewhat greater voltages. The pressure would increase slightly at each successive lamp in the direction of the switch; lamp C would receive the highest pressure of the group.

In practice the location of the load center is seldom determined by calculation. An approximate location is assumed, the position of which is determined by inspection of the loads on the circuit and their positions. Considerable experience is necessary before the center can be thus located by inspection with a fair degree of accuracy. The beginner should compute several cases until he is familiar with the principles involved. A high degree of accuracy in the location of the load center is not essential, because there are other factors entering into wiring calculations that usually cannot be accurately determined.

The load center of a group of receivers symmetrically arranged and all of the same capacity will be in the middle of the group, as indicated in Figs. 1 and 2. The distance denoted by D in the wiring calculation formula is the distance from the beginning of the circuit under consideration to the load center, measured along the circuit.

The load center of a group of receivers unsymmetrically located or of unequal capacities is found by first multiplying the normal-ampere capacity of each receiver by its distance from the beginning of the circuit under consideration, second, adding all these products together, and third, dividing this sum by the total current of the circuit. The quotient thus obtained will be the distance in feet of the load center from the starting point of the circuit. In Fig. 3 there are three loads of 100, 40 and 20 amperes located 80, 100 and 130 ft. respectively from the switch S at the source of supply. To find the location of the load center as explained in the foregoing, first multiply the distance in feet each load is from the beginning of the circuit, by the normal amperes of the load corresponding to each distance. Thus:

80 ft. × 100 amp. = 8,000 amp.-ft.
100 ft. × 40 amp. = 4,000 amp.-ft.
130 ft. × 20 amp. = 2,600 amp.-ft.
Total, 160 amp. 14,600 amp.-ft.

Then the total ampere-feet divided by the total current is 14,600 ÷ 160 = 91.25 ft., equals the distance the load center is from the beginning of the circuit as shown in the figure.

Instead of measuring all the distances from the beginning of the circuit, they can be measured from the first receiver of the group; then the resulting distance to the load center will be measured from the first receiver of the group. The example Fig. 4, illustrates this method. Multiplying the distance in feet of each receiver from the first load by each load in amperes, the result is:

0 ft. × 100 amp. = 0 amp.-ft.
20 ft. × 40 amp. = 800 amp.-ft.
50 ft. × 20 amp. = 1,000 amp.-ft.
Total, 160 amp. 1,800 amp.-ft.

Then dividing the total ampere-feet by the total amperes, 1800 ÷ 160 = 11.25 ft., equals the distance in feet from the first load to the load center. This value plus the distance from the beginning of the circuit to the first load is the distance that the load center is from the supply end of the circuit, in this case equals 80 + 11.25 = 91.25 ft., as indicated in Fig. 4. This result is the same as that obtained with the method given in Fig. 3. However, it should be noted that these methods are not absolutely correct, because they assume that each receiver takes its normal current. This assumption is not a true one, because the voltage at the farther end of a circuit is lower than that at the near end. Consequently, the same lamps or other receivers will pass more current if located at the near end of the circuit than at the far end. Nevertheless, these values are accurate enough for use in wiring calculations.

Where no energy is taken from a circuit except at its end, the distance D used in the formula for circular mils, is the entire length of the circuit. This is illustrated by the example in Fig. 5. Here the only load on the circuit is one of 100 amperes at the end of the line, 250 ft. from the supply main. Then the load center is at the point AA in the circuit, or where the load is located. With a 100-ampere load and a 5-volt drop in the line, the size of conductors required is

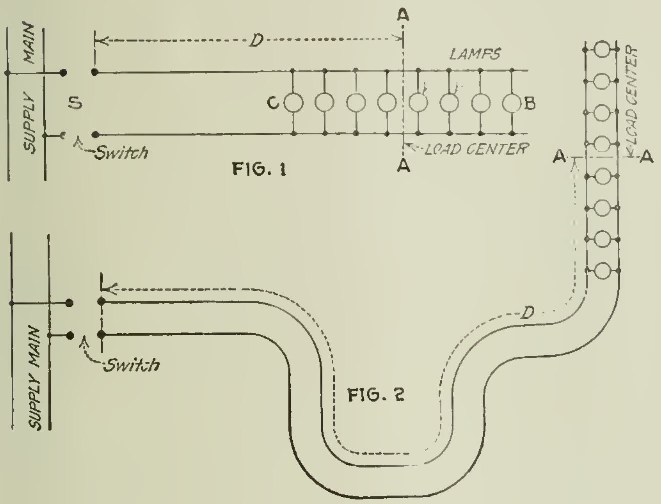
$$cir.mils = \frac{22DI}{E_d} = \frac{22 \times 250 \times 100}{5} = 110{,}000$$

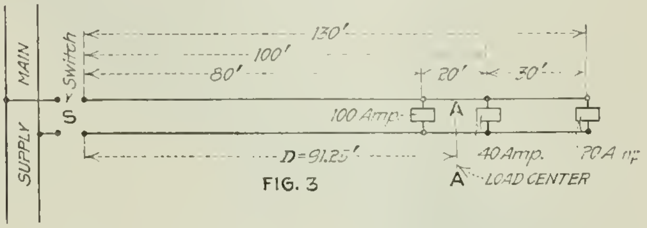
The problem, Fig. 6, will further illustrate how a load-center value is used and is typical of those which are often encountered in practice:

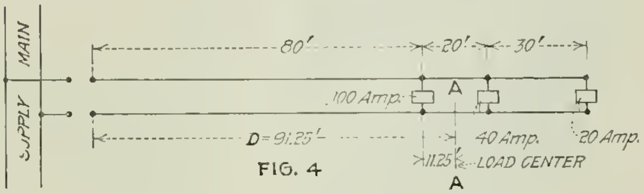
A direct-current circuit is to supply a total load of 155 amperes. This is subdivided into minor loads of 35, 15, 60 and 45 amperes, located respectively 180, 200, 280 and 325 ft. from the source of energy, as indicated in the figure. The permissible drop in the circuit is 5 volts. Where is the load center located? What size conductors should be used to insure that the drop to the last load on the circuit (the 45-ampere load) will not exceed the permissible drop $Ed = 5$ volts?

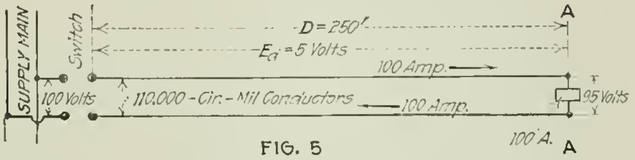
To find the location of the load center the procedure indicated in Fig. 3 may be followed, thus:

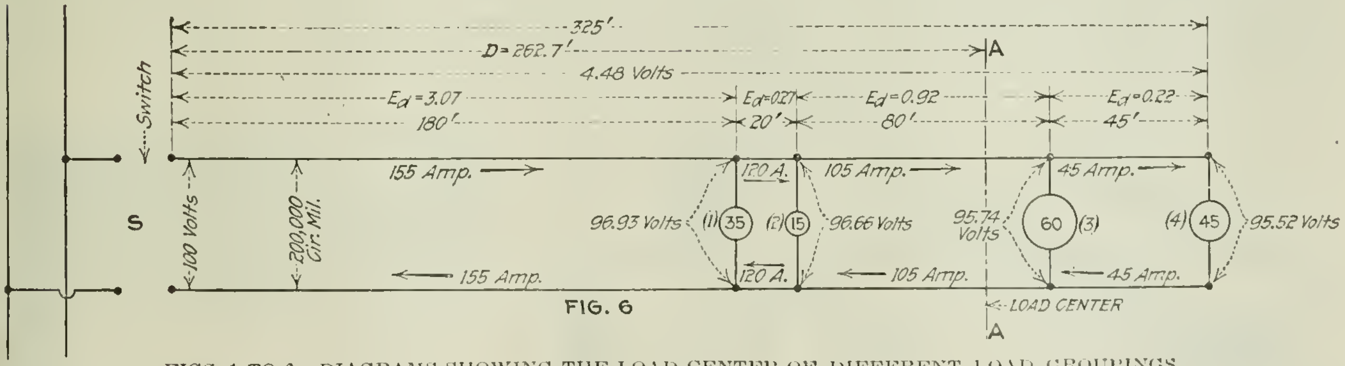
180 ft. × 35 amp. = 6,300 amp.-ft.
200 ft. × 15 amp. = 3,000 amp.-ft.
280 ft. × 60 amp. = 16,800 amp.-ft.
325 ft. × 45 amp. = 14,625 amp.-ft.
155 amp. 40,725 amp.-ft.











FIGS. 1 TO 6. DIAGRAMS SHOWING THE LOAD CENTER OF DIFFERENT LOAD GROUPINGS

The total ampere-feet divided by the total amperes is 40,725 ÷ 155 = 262.7 ft. approximately. Therefore, the load center is the distance $D = 262.7$ ft., as shown in the figure, from the source of energy. The current I is 155 amperes, then the size of the conductors required to not exceed the 5 volts drop in the line is

$$cir.mils = \frac{22DI}{E_d} = \frac{22 \times 262.7 \times 155}{5} = 179{,}161$$

The next size larger standard conductor is 200,000 cir.mils. and is the size that will have to be used. This size conductor will give a slightly less volts drop in the line than the size calculated on account of having less resistance.

The volts drop and current in the different sections of the circuit, the distances and the voltage at each receiver, are shown on the figure. The total drop to the last load is 4.48 volts. The drop in each section was computed by the formula:

$$E_d = \frac{22DI}{cir.mils}$$

where D is the length in feet of each section. Hence the volts drop in the first section is $E_d = \frac{22 \times 180 \times 155}{200{,}000} = 3.07$ volts,

in the second section, $E_d = \frac{22 \times 20 \times 120}{200{,}000} = 0.27$ volt,

in the third section, $E_d = \frac{22 \times 80 \times 105}{200{,}000} = 0.92$ volt,

and in the fourth section, $E_d = \frac{22 \times 45 \times 45}{200{,}000} = 0.22$ volt.

The difference between the voltage at the switch and the volts drop in the first section will give the volts at load No. 1, or 100 — 3.07 = 96.93; the difference between the voltage at the first load and the volts drop in the second section will give the volts impress at the third second load, or 96.93 — 0.27 = 96.66 volts; at the third load the volts equal 96.66 — 0.92 = 95.74 volts; and at the last load the volts equal 94.74 — 0.22 = 95.52 volts. This makes the volts drop in the line 4.48 instead of 5, as assumed at the beginning on account of the conductors being slightly larger than the theoretical size calculated.

"John Crane" Flexible Metallic Packing

Flexibility and compressibility are necessary features in a packing which must also possess the ability to prevent pressure from leaking past it. In order to meet these requirements, the "John Crane" flexible metallic packing is made by taking long thin continuous strips of metal foil and wrapping them spirally around and around and back and forth and coating each sheet with a layer of lubricant, Fig. 1, the purpose of which is to permit the metal strips to slide on each other and to allow bending about the smallest diameter rod and at the same time giving it compressibility sufficient to compensate for wear and to control any leakage at ordinary pressures.

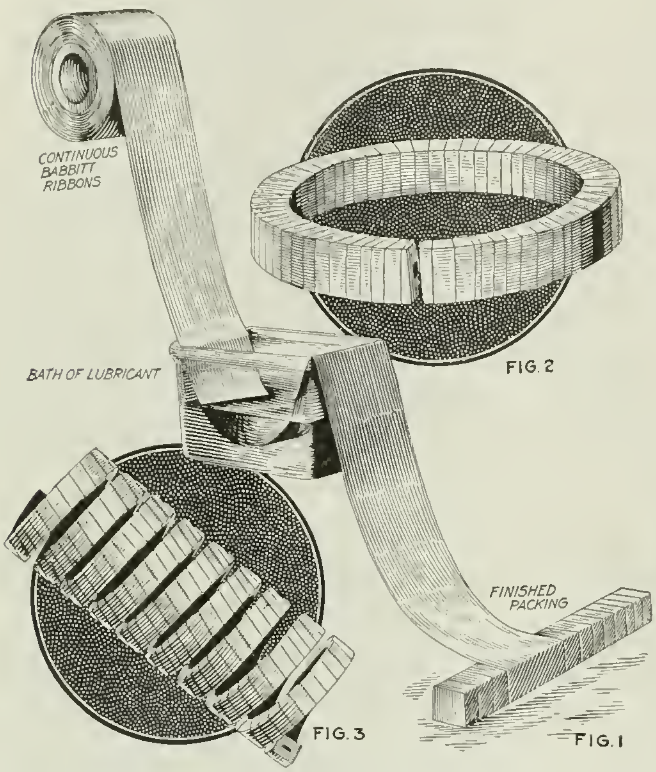


FIG. 1. LUBRICATING THE METAL STRIPS. FIG. 2. RING PACKING. FIG. 3. SPIRAL PACKING

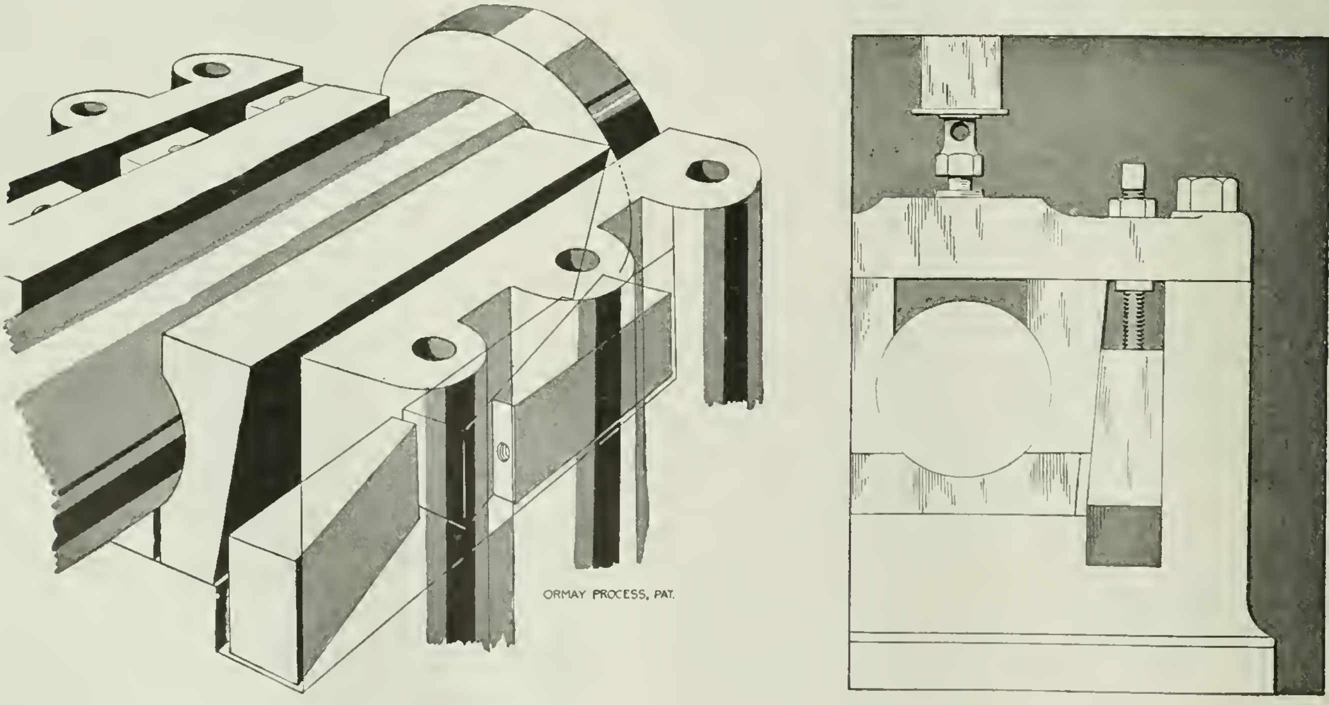
The antifriction metal of which the packing is made is so soft that it can be easily cut with a knife and it will take any shape. This packing, made by the Crane Packing Co., 29 South Clinton St., Chicago, Ill., is in a large number of forms, such as straight lengths, rings, and spirals, from $\frac{1}{32}$ in. to 2 in. in size. It is suitable for steam, ammonia, hot and cold water, both high- and low-pressure; hydraulic, oil and acid service. The ring and the spiral forms of packing are shown in Figs. 2 and 3, respectively. The rings are generally preferred for large plungers, and the spiral coils are used on small work, such as valves and small steam rods.

Removing Main-Bearing Quarter Blocks

Lacking the right "twist of the wrist," a simple job sometimes becomes an ordeal. For example, it became necessary to remove the quarter blocks from the main bearing of a Buckeye engine. After taking off the cap and dropping the three adjusting wedges as far as they would go, the bearing would not lift out. The wedges were "big end down" and would not come out, of course; the governor was over too close to allow them to come out sidewise, and to shift the governor over on the shaft was "some job"—this was done once, but was not bragged about later when the right way was found. The fact that this (shifting the governor) was done by the engineering staff of a steel company seems to justify writing this. All there is to getting the wedges out of the way is to move two of them over to one side enough to allow the other to be laid over on its side (small end toward the others) then the middle one can be laid over alongside of it (small end toward the large end of the first one) and pushed over enough to allow the third one to be laid over on its side. This leaves "all kinds of room" to handle the quarter block.



ADJUSTING WEDGES LAID OVER ON SIDES OUT OF THE WAY

Favorable Performance of High Setting

By H. L. Strong

Though modern practice has proven the desirability of setting boilers well up from the fire and leaving ample room for the complete burning of the gases, it seems difficult for many to grasp the idea and apply it in practice, especially when applied to horizontal tubular boilers.

I have found that low settings, especially for boilers that are forced, give the following troubles: Reduced capacity, less efficiency, smoke, severe conditions for the fire sheets, rear tube sheets and tube ends, also severe service for the firebrick linings, and excessive deposits of ash in the combustion chamber, which become fused and difficult to remove. New River coal is used. We have in our plant four 90-in. return-tubular boilers set 38 in. above the grate, and it requires careful firing to obtain 12 per cent. CO_2. The flow meters will register 800 hp. on heavy driving. The outside lap of the first girth seam on all four boilers became burned and cracked and it was necessary to electrically weld the seams and rivets.

The combustion chambers fill rapidly, and we have to loosen the deposit with a pick and clean it out at least every fourth week. The firebrick linings deteriorate rapidly, and ash deposits fuse onto the walls back to and including the rear wall and have to be broken off with picks and bars. These are hand-fired boilers having shaking grates, set level. With the exception of the height of setting and level grates, these boilers are identical with the setting of the fifth one of this type, which we installed during the summer of 1917 and which is described here. The new boiler is set 5 ft. 4 in. above the dead plate. The grate is of the shaking type, built in four sections, and half of each section shakes separately. The grate is 7 ft. deep and 12 ft wide, the furnace design being such that the grate projects 2 ft. 3 in. beyond the boiler on each side. The grate pitches to the rear one inch to the foot, or seven inches in all. The height from the rear end of the grate to the shell is 5 ft. 11 in.; height of bridge-wall, 2 ft. 3 in. A considerably higher bridge-wall was tried in connection with a hand stoker grate having 1 ft. 8 in. pitch in 7 ft., but the heat was so intense that it melted out this bridge about as fast as we could repair it. The distance from the bridge-wall to the shell is 3 ft. 8 in.; extreme height of furnace, 8 ft. 9 in.; distance from combustion-chamber floor to shell, 6 ft. 6 in.; from rear head to rear wall, 2 ft. 8 in.; width of combustion chamber, or setting beyond grate, practically the same as the diameter of boiler, or 90 in.

Unfortunately, we made no test of this boiler, and some valuable information is therefore not available. This boiler raises steam from cold water quicker than the lower-set boilers. The capacity is greater when driving on peak loads; for under conditions where the others do 800 hp., the new one frequently shows 1000 hp. on the flow meter. Any reasonably good firing will maintain 15 per cent. CO_2 on the recorder, and I have never yet found more than a trace of CO. The extreme variation of load and consequent draft irregularity (0.25 in. to 0.5 in. over the fire) is favorable to CO production, too. The accompanying CO_2 chart was made on an ordinary run. Between 6:15 and 7:15 p.m. the fire was cleaned, which accounts for the condition shown. We allow one hour from the time cleaning is started until the fire is again in working order. When it is understood that this fire, burning New River run-of-mine coal and carrying 0.5 in. draft over the fire, is about twelve inches thick, it will be appreciated that cleaning 84 sq.ft. of grate and trimming off the clinker is not an easy job.

When in doubt about the accuracy of our recorders, we check them with the Orsat, and at the time this chart was made the recorder agreed exactly with the Orsat. Some years' experience with gas analysis has convinced me that a high percentage of CO_2 is not so dangerous to economy as many think, especially when there is careful and efficient supervision. I have found the worst cases of CO in samples having 12 to 13 per cent. CO_2 If a recorder shows 15 to 17 per cent. CO_2, it is fairly safe to say that there is not much, if any, CO present. I do not recall that I ever found over 1 per cent. CO in a sample of 15 to 17 per cent. CO_2 and more frequently none; I have, however, found 4 per cent. CO in samples containing 12 or 13 per cent. CO_2. During the 24-hour period of this CO_2 chart, the lowest uptake temperature (aside from the cleaning period) was 400 deg. F., the highest 525 deg. F. and the average 474.2 deg. F.; the average temperature of the fireroom, 75.7 deg. F.

[The performance between 3 a.m. and 12.30 p.m. that is, 15 per cent. CO_2 or better without a break, is indeed commendable for a hand-fired plant; in fact, it is a remarkable performance.—Editor.]

What Your Red Cross Dollars Do*

LESS than a year ago the Red Cross called upon the American people for a fund of $100,000,000 with which to finance the tremendous work of relief and reconstruction that was vital to our Allies and ourselves, if the German terror was to be beaten back.

And so the call came for the First War Fund, and in one week America's answer went echoing back to Europe—more than a hundred million was freely given to make the world fit for democracy. At that time the membership of the Red Cross was less than two million. In six months it had increased to five million and with the Christmas membership drive the enrollment sprang in one mighty bound to 22,000,000 loyal supporters of this perfect embodiment of the nation's purpose in this war.

Today the American Red Cross is the largest organization of any kind in the world and the greatest force for good. In the black welter of warring nations it is the one bright spot of Hope—Humanity's Light.

With such a vast working force behind it there will never be any doubt that the tremendous work, which in the last twelve months has been barely started, will be upheld and continued throughout the war until its ravages have been restored. For this purpose the American people are going to be asked to contribute $100,000,000 more during what is known as the Second Red Cross War Fund Week, May 20-27.

But with each call for funds the question naturally arises as to where these millions go, and since twenty-two million members have a right to know how their money is being spent, the following gives in brief what the first War Fund has been appropriated for up until Mar. 1, 1918.

FRANCE, $30,936,103.04

Established infirmaries and rest stations along all routes followed by the American troops in France.

Built canteens for use of French and American soldiers at the front, also at railroad junctions and in Paris.

Supplied American troops with comfort kits and sent them Christmas gifts.

Established a hospital distributing service that supplies 3423 French military hospitals and a surgical dressing service that supplies 2000.

Provided an artificial-limb factory and special plants for the manufacture of splints and nitrous oxide gas.

Established a casualty service for gathering information in regard to wounded and missing.

Opened a children's refuge hospital in the war zone and established a medical center and traveling dispensary to accommodate 1200 children in the reconquered sections of France. Fifty thousand children throughout France are being cared for in some measure by the Red Cross.

Planned extensive reclamation work in the invaded sections of France from which the enemy has been driven; this work now being carried out with the coöperation of the Society of Friends and an alumni unit from Smith College.

Established a large central warehouse in Paris and numerous distribution warehouses at important points from the sea to the Swiss border for storing hospital supplies, food, soldiers' comforts, tobacco, blankets, clothing, beds and other articles of relief.

Secured and operate 400 motor vehicles for the distribution of supplies.

Opened a hospital and convalescent home for the repatrie children at Evian; also established an ambulance service for the adult repatries who are now returning from points within the German lines at the rate of 1000 a day.

Organized a nurses' service for American Army use.

Established twenty dispensaries in the American Army zone to improve health conditions in that section before the coming of American troops.

BELGIUM, $2,086,131

Erected warehouses and stores to serve as centers of relief distribution.

Started reconstruction work in reconquered territory, supplying repatriates with temporary dwellings, tools, furniture, farm animals and supplies essential to giving them a fresh start in life.

Appropriated $600,000 for the relief of Belgian children, covering their removal from territories under bombardment and the establishment and maintenance of them in colonies.

Provided funds for the operation of a hospital for wounded Belgian soldiers and for part of the equipment of a typhoid hospital.

ITALY, $3,588,826

Provided the Italian Army with three complete motor-ambulance sections comprising sixty ambulances, forty trucks and 100 American drivers.

Contracted for 10 field hospitals complete for use by the Sanita Militaire and the Italian Red Cross.

Supplied 1,000,000 surgical dressings. Opened relief headquarters in nine regional districts of Italy.

Established a hospital for refugees at Rimini.

Planned and made appropriations for extensive work among the refugees in all parts of Italy.

RUMANIA, $2,676,369

Rushed more than $100,000 worth of medical supplies and foodstuffs into Rumania immediately after the retreat to Jassy.

Carried general relief work into every part of the stricken country not invaded by the Teuton and Bulgarian forces.

UNITED STATES, $8,589,899

Organized and trained 45 ambulance companies, totaling 5580 men, for service with American soldiers and sailors.

Built and maintained four laboratory cars for emergency use in stamping out epidemics at cantonments and training camps.

Started work of eradicating unsanitary conditions in the zones immediately surrounding the cantonments.

Established camp-service bureaus to look out for comfort and welfare of soldiers in training.

Supplied two million sweaters to soldiers and sailors.

Mobilized 14,000 trained nurses for care of our men.

Established a department of Home Service and opened training schools for home service workers.

Planned convalescent houses at all cantonments and training camps. Increased membership from a scant half million to approximately 22,000,000.

OTHER DISBURSEMENTS

For War Relief in other countries, including Great Britain, Russia and Serbia, $7,581,075.

To supply food to American prisoners in Germany, $343,304.

For supplies purchased for shipment abroad and for advances to chapters for material, $15,000,000.

Equipment and expenses in United States of personnel for Europe, $113,800.

Restricted as to use by donors, $2,500,410.

Working cash advanced for France and United States, $4,286,000.

Making a grand total of approximately $78,000,000.

To those who care to study the details of how each penny has been spent, printed statements covering all War Fund appropriations are obtainable from Chapter chairmen.

The foregoing covers some of the principal battle grounds in the Red Cross War against want and misery, but other millions are being constantly appropriated to meet new needs as they arise, and the War Fund must be replenished, for it is inconceivable that such work should ever be allowed to suffer for the lack of mere money.

Give to your Red Cross until your heart says stop—it is the Heart of the World.

---

Editorials

How About Next Winter?

IF REPORTS are any indication, the coal situation is far from satisfactory. To say the least, conditions are anything but reassuring, and the possibilities of experiencing a fuel shortage during the coming winter, as we did last, have not by any means been entirely removed. The Fuel Administration has been putting into effect very elaborate and no doubt effective plans and probably is doing all that is possible to meet the emergency so far as getting coal out of the mines and delivering it to the consumer. However, there is another side to the question—how the coal is utilized after being delivered to the consumer—and this is just as important to think about just now as the delivery of the coal. since every ton saved during the summer is a ton available next winter.

Almost simultaneously with an announcement that the coal situation was critical, the restriction on the use of advertising illumination was removed. Would it not have been more in-keeping with the seriousness of the fuel problem to have continued the restrictions until such times as we might look forward with some feeling of certainty that coal would be forthcoming next winter, when it is an absolute necessity to human existence in cold climates?

Preston S. Millar, in a paper presented before the Illuminating Engineering Society in New York City, February 15, pointed out that the net coal saving thought desirable through curtailment of lighting was equivalent to seven per cent. of twelve million tons used for the production of light by electricity, or eight hundred and forty thousand tons. The author expresses the opinion that the saving possible through the curtailment of light is so small compared with the coal saving possible by other adjustment as to make that obtained by the curtailment of lighting of little consequence.

However, we must not overlook the fact that this saving is obtained after increasing industrial lighting fifty per cent. above the standard at that time, and increasing protective lighting two hundred per cent. If industrial lighting had not been increased as suggested by Mr. Millar, but maintained at its present standard, it would have made possible a total saving of approximately sixteen per cent., or two million tons of coal per year. But allowing that it is possible to save only eight hundred and forty thousand tons per year by lighting curtailment, this is something more than an insignificant item. If this amount of additional coal had been available last winter and had been used for heating homes, at least eight hundred and forty thousand families could have been kept warm for a month. Or if used for industrial lighting and power purposes, many of the industries that were forced to shut down or curtail their output for considerable periods last winter could have run at full capacity.

The fact that if each family in this country would decrease by one shovelful its daily use of coal the result would be an annual saving of fifteen million tons looks simple at first thought, but we must not overlook the fact that last winter tens of thousands of families in this country did not have the one shovelful to save and would have been only too glad to have had some of the six hundred thousand tons used for advertising illumination.

Let us not forget that there is another winter not very far ahead of us, and that all the time the demands for light and power in industries essential to the winning of the war are increasing. If the high rate of production that these industries have been establishing this last month or so is to be kept up the year around, it is absolutely necessary that they have an uninterrupted coal supply for light, heat and power and that the employees have comfortable homes during the cold season as well as in the summer. Until it is absolutely certain that the coal supply is adequate to meet this demand, it would seem that we can do with somewhat dimmed white ways, which have become a part of our city life.

Pseudo Data

C. E. STROMEYER is reported in *Engineering* to have said during discussion of a meeting of the Institute of Mechanical Engineers, London, that personally he disliked associating boiler insurance with boiler inspection. As an instance of how insurance worked, he stated that in America there was no association which corresponded to those in England whose first duty is to inspect. The American boiler-insurance companies he said, published at intervals a leaflet giving the number of boiler explosions, the standard being the number of deaths caused. In England, for insured and inspected boilers, there were ten deaths per annum as against two hundred in America. That illustrated the significance of inspection.

As reported, the figures are significant of nothing. We do not question but that per unit number of boilers in service, we in America have more boiler explosions than occur in England. The excellent supervision by the Board of Trade and the service to members by the Manchester Steam Users' Association, for which Mr. Stromeyer is chief engineer, are influential factors in preventing boiler accidents. But data, or more correctly, perhaps, statistics, given or reported in such loose manner were better unsaid. The reader or listener should know what is considered as an explosion, what relation the terms of the ratio 10: 200 deaths per annum bears to the total number of boilers installed or in service in the two countries respectively.

The trend of business makes it increasingly important that engineering data be comprehensible as well as exact. This applies not only to such cases as the one cited, which is used merely as an example, but to data in general, and especially those presented in society papers. No national good can come of giving information that is subtle and that is used to achieve victory in argumentation for some proposals or practice regardless of their engineering truth either as pure science or as related to other conditions necessary to their industrial application.

Pseudo facts may well be used by lawyers (though by every consideration of justice and honesty they should not be); but these are wrong in engineering—wrong ethically and socially. In his most interesting book, "The Great News," which contains so many captivating phrases, but which one may gently criticize as a little too intangible, Charles Ferguson has a statement that applies well here, namely: " . . . there is absolutely no social will-power directed to the upkeep and improvement of the apparatus of civilization." The point is that each of us is too much concerned about making good our particular case, however much harm may be done or confusion created broadly.

The Golden Rule must be dragged out of a musty book, sincerely embraced and frankly applied by the professions and the trades—not in parlor discussions and philanthropical endeavors alone, but all during the working day. It must dull the narrow, personal and selfish conscience and stimulate the broad, national conscience to which the war's hardships and magnitude have given new life. Certainly the great blessing of the war will be the honest, altruistic coöperation and coördination of the forces of civilization to make the world a better place to live in. When each nation, bleeding, hungry and poor, emerges from the long struggle and turns to look over its shoulder at the fields and seas where lie its young and honored dead, it will resolve that nevermore shall science be the handmaid of holocaust; but rather that it shall serve the peaceful arts so well that the incentive which gives birth to wars will starve into extinction. To even make a good beginning, facts must be presented so as to be exposed top, bottom and all sides.

Looking Ahead

FROM coal heaver to general manager seems a long uphill climb—a journey that many begin and few finish—yet it is suprising how quickly some make the trip. It seems but yesterday that they were heaving coal and sweeping tubes, yet ten years have slipped by, and today they are directing the management of the whole plant and ever planning for improved conditions and greater things. These men kept their eyes front. By this it is not meant that they dared not glance sideways, but that they had a fixed goal—a beacon ahead upon which they kept their eyes fixed in order to steer the course that they knew would shorten their trip to that harbor of Success. These fellows were never afraid to tackle a job, no matter how much energy it required. To be sure, they must have had times when they questioned themselves as to whether they were capable of doing it—this is just what gave them confidence.

Never before in the history of this great nation has there been such a demand for men who can handle big tasks. Some of the ablest men in the field have gone to Washington and into the service of the country. Their posts in the plant had to be filled by their trained subordinates, which in turn meant a general shake-up all through the various grades in the plant, and those who were capable and ready were boosted up a step—sometimes two.

Our great merchant marine is incessantly calling for engineers with ability and courage; already it has made large inroads on the staffs of the power plants throughout the country.

Great shops and industrial centers have developed with astounding rapidity. One stops to wonder where they got the men with ability to fill the many positions of responsibility. It does not require much study to find where they came from. They were ready to answer the call—up from the ranks to take command. They were men who had faith in their ability to develop themselves by study and increasing work. Where are you in this great change that is being wrought? Surely, you cannot be still thinking that there is no show—no opening for you—no chance to get into a better job. The only bid you can make for that better job is to outgrow your present one.

You would not now be reading this article if all your ambition were dead. You would not have this magazine in your hands if you were not trying to find something that would help you. Men don't read technical papers for pastime—they do it to keep informed and to better themselves.

The Coal-Zoning Plan

THE importance of an adequate coal supply in the winning of the war cannot be minimized or ignored. Decreased or interrupted production may result in stoppage of industries engaged on war contracts, the enforced idleness of labor, and eventually a condition similar to that of last winter, when thousands of homes found themselves without heat.

The zone system of coal distribution put into effect by the order of the United States Fuel Administration represents a serious and at the same time an ambitious attempt to cope with the difficulties of the fuel situation. It is not the outcome of ill-advised haste or snap judgment, but rather a plan resulting from months of study and careful consideration.

It would be futile to expect that a scheme so far-reaching in its scope could be put into effect without some disruption of established relations. The urgent necessity for diminishing the burden on transportation facilities involved restrictions and prohibitions that had previously been unknown; but wherever it could be done, long-established trade relations were preserved, since this would reduce the confusion and disorganization attendant upon the adoption of the new plan.

So many interests must be considered in the working out of a successful scheme of fuel regulation that the situation is exceedingly complex, and so it becomes necessary to provide for a certain measure of flexibility in order to meet changing conditions and unforeseen emergencies. This has been done by providing for a system of special permits to be issued by the Fuel Administration whenever circumstances warrant. Thus, while the zone system as announced may show faults and imperfections as it comes to be more widely applied, the special-permit provision makes possible a prompt adjustment to prevent injustice or unnecessary hardships.

Correspondence

Second-Hand Boilers in Bad Shape

A few months ago I took charge of a plant where they were installing a second-hand Scotch marine boiler that had been purchased by the general manager from a second-hand dealer who represented that it had been inspected by a state and also by an insurance inspector and passed to carry 110 lb. pressure. I made a thorough inspection of it and found things in good condition until I crawled into the combustion chamber, and there I saw a sight.

The ends were burned off from about three-fourths of the tubes, and some of them were so badly corroded that they only stuck halfway through the tube sheet. The leakage had been so bad that sediment almost choked up some of the tube ends. How inspectors could have passed the boiler if they inspected it at all, and I don't believe they did, is more than I can say. We had to remove the tubes, have ends welded on, and replace them again before the boiler was fit for service. This cost the company about two hundred dollars besides the trouble and delay in getting the boiler into service. It is in good condition now and giving satisfactory service, but the incident goes to show that it is mighty dangerous and expensive for a man without practical knowledge of boilers to buy second-hand ones without having a thorough inspection made. S. A. REILLY.

Orrville, Ohio.

Saving Ammonia and Coal

Nearly all engineers know that they should not try to save ammonia by not putting in the proper charge at the beginning of the season. One can make up for a weak or insufficient charge only at the expense of the coal pile. This applies to absorption machines particularly. They are commonly run with insufficient ammonia, as it is so easy to get the capacity by circulating a little more weak liquor per pound of anhydrous needed to do the refrigerating.

This is bad practice. The weight of weak liquor circulated per pound of anhydrous should be kept as low as possible, say 6 to 7 lb.; 12 or 14 lb. is not unusual in some plants.

The speed of the aqua pump should be as steady as possible. Most manufacturers furnish a regulator to care for this pump.

With coil absorbers with the separate mixer on each coil there is a tendency for the liquid to "dump" or come in irregularly. When this happens, there occurs a loss due to not having the strong liquor from the pump to the generator at as high a temperature as it would have if it had passed in a steady flow through the exchanger and analyzer. The flow of weak liquor from the generator through the exchanger is almost constant, and for the exchanger to heat the strong liquor as much as possible and cool the weak liquor also, both must pass in a steady flow.

Although machines fitted with this type of absorber have a large aqua receiver which helps to take care of irregularities, the men will often give the pump too much steam, causing too fast a flow of liquid. Where such conditions obtain, I would disconnect the regulator and let the men control the pump by hand; they will soon get it set so it will not stop and race.

I know of one plant where the irregular speed of the aqua pump caused the temperature of the exchanger to vary so that one of the head gaskets blew out, with a loss of some ammonia and loss of the machine for four days during the summer's rush. Keep the pump operating steadily and watch the liquid seal on the ammonia receiver so as not to blow any gas over in the cooler or ice tank. Every pound of gas carries with it the latent heat plus the superheat.

Keep the strong-liquor pump rod packed so as not to leak ammonia out and air into the system and you will have little trouble with non-condensable gases, which always cause some loss of ammonia when purging.

Make it a rule when you go on watch to look things over, then take your sulphur stick and examine the machines for leaks, for many small leaks will go unnoticed if one depends only on one's nose to find them, especially if coils are located on the roof.

Machines with double-pipe or submerged cooling coils, where the ammonia from a leak will be absorbed by the water or brine, make it necessary to test this brine and water with Nessler's reagent. This should be done at least three times a week.

The formula for making Nessler's reagent was published in the Jan. 15, 1918, issue of *Power* and may be found in most handbooks on refrigeration. Sensitive paper is useful for locating leaks on the water side of the machine, but cannot be depended upon in calcium brine, as such brine turns the paper red whether the brine does or does not contain ammonia.

Jersey City, N. J. BERNARD LAMB.

Horseshoe Magnet a Handy Tool

The suggestion, by W. H. Bennett, page 447 in the issue of Mar. 26, for removing drill chips is a good one. I have also found that a horseshoe magnet, one taken out of an old house telephone for instance, is mighty useful for the same—and many other purposes. If the magnet is too large to go into the hole, it can be put in contact with a small rod as an extension or the rod can easily be magnetized if near a plant that has magnetizing coils.

Two or three magnets tied together will be found useful to wiremen when a knife, screwdriver, pliers or other tool is accidentally dropped down an open partition as sometimes happens. Just lower the magnet on a string until it comes in contact with the tool, then "haul away." R. L. PETERSON.

Knoxville, Iowa.

Home-Made Pipe and Drilling Vise

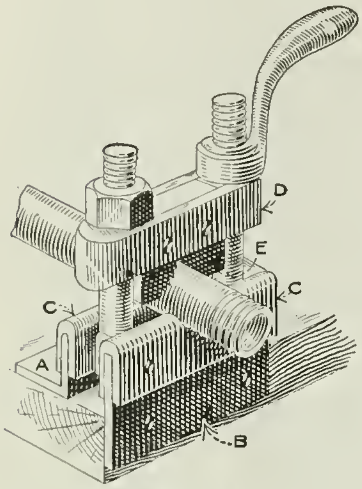

FIG. 1. DETAILS OF CONSTRUCTION

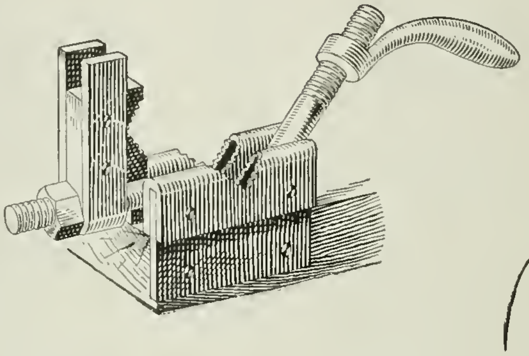

FIG. 2. VISE SHOWN IN THE OPEN POSITION

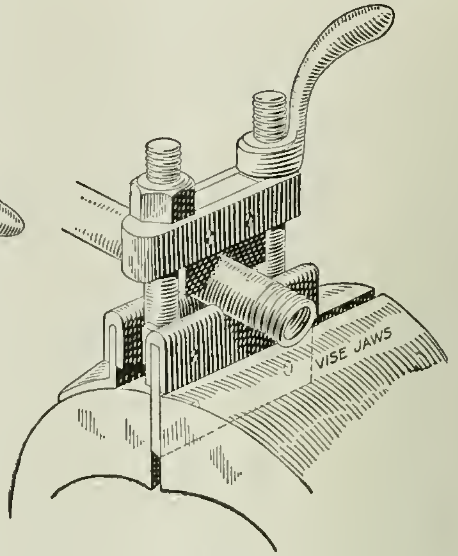

FIG. 3. CLAMPED BETWEEN VISE JAWS

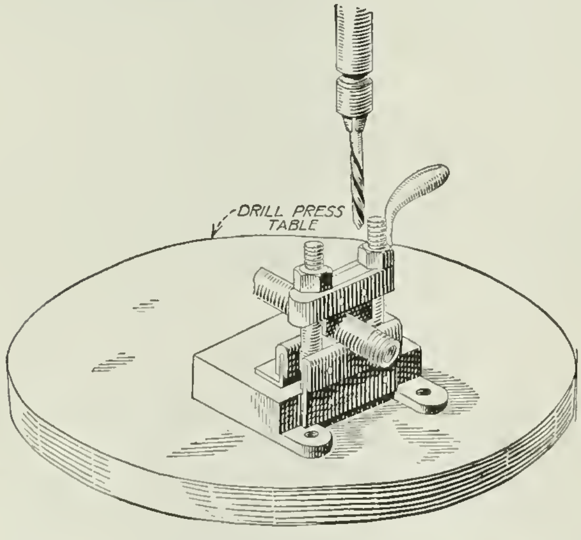

FIG. 4. VISE CLAMPED TO DRILL-PRESS BED

A handy pipe vise that can be made by any engineer who is not in a position to purchase one is shown in the accompanying illustrations. The grip on pipes should be, as much as possible, around the entire cylindrical surface, otherwise the pipe is easily scored. The device described was built in three sizes. The largest size, fitted with brass jaws, is used for gripping small pipe or rods for various light operations. When mounted on a block, Fig. 2, it serves as a handy vise for drilling round stock. It can be attached directly to the bench, Fig. 1, or gripped in the vise, Fig. 3, for threading, or clamped to a drill-press bed for drilling holes in round stock, Fig. 4. The vise is composed of two plates. Plate *A*, Fig. 1, is made of angle iron for fastening to a block or bench; *B* is of steel plate of the same length and can be used for fastening to a bench or for being gripped between the jaws of a bench vise. Both pieces are reinforced on the upper edge by a piece of steel, *C*, riveted on. In the center of these assembled plates a V-shaped way is sawed, which is provided with fine teeth for gripping purposes. The movable jaw *D* is made from a U-shaped strap, in the center of which is riveted a solid block *E*. This upper jaw is guided between the two lower jaws by means of a bolt pivoted between them, as shown. A handle nut is also provided for quick action in opening or closing.

Burning Fuel Oil

Why do we not get more articles on the subject of burning crude oil? Plants in both Texas and California are large users of fuel oil, and in a great many small plants it is burned very inefficiently. Engineers of large plants are beginning to realize that large combustion chambers give the best results, and when setting new boilers, raise them from two to three feet higher than the old-style setting. The bridge-wall is placed about ten feet back from the doors, and the grates are covered with loose firebrick. Most of the air should be admitted under and on each side of the burner, with just enough admitted under the flame to raise it away from the grate and keep the grate cool.

As every engineer knows, an excess of air means a loss in economy and all brickwork is more or less leaky. By using the damper to control the air supply, the difference in pressure between the inside and outside of the setting can be kept at the lowest point.

With from 3½ to 4 sq.in. of clear air space through the grates for each normal horsepower rating, a draft from 0.05 to 0.1 in. of water next to the damper is sufficient to give air enough to carry better than normal rating on the boiler, and certainly there won't be as much air leakage as when the ashpit doors are used to control the air supply and a difference of from 0.3 to 0.4 in. is maintained between the inside and outside by leaving the damper wide open. L. D. **Harris.**

Houston, Tex.

Fires in Turbo-Generators

M. A. Walker's article on "Fires in Turbo-Generators," in *Power*, issue of Jan. 22, is, I believe, a live subject and one worthy of serious consideration. As Mr. Walker points out, the modern turbo-generator contains material that will burn and, once ignited, makes a difficult fire to fight on account of its location and the great amount of blinding and suffocating smoke given off.

My experience has convinced me that one of the best preventives of these fires is to get the machine off the line and kill the field at the first sign of trouble. I have seen four or five cases where doing this prevented a fire, and others where it was not done caused serious fires, totally destroying the insulation on the ends of the stator coils, besides damaging the tie rings and laminations.

The first cases that came under my observation were on 4500-kv.-a. 13,200-volt three-phase 60-cycle machines. On the first machine to give trouble, the insulation broke down on the top coil in a slot, and burned this coil off, damaging the insulation of the bottom coil and the top coil in an adjacent slot. These three coils had to be taken out; two were reinsulated on the job and put back, and a third had to be replaced by a new coil. In three other cases in this plant we lost from one to three coils in like manner, all of these breakdowns being near the center of the slot length.

Practically all these burnouts were preceded by line trouble causing a heavy surge, and as there were no reactances in the line, the generators received the whole strain. The first indication of trouble would be a groan from the generator, then a few sparks mixed with dust. As these machines had an air outlet on top that was easily seen by the switchboard operator, he generally discovered the trouble when it first started and cleared the machine.

In one case there was a new operator on the board; two machines were in parallel when the trouble started. The switchboard attendant tried to prevent interrupting the load by holding the defective unit on the line until the engineer brought another machine up to speed. The result was that both coils in one slot were completely burned out, copper and all, and the insulation at each end of the winding was set on fire.

These generators had small plates near the top of each end bell, giving access to the inside of the machine. Although these covers got almost red-hot, we succeeded in removing them and in a short period had the fire out by the use of two ¾-in. water hose—but not before the insulation was entirely ruined on both ends of the winding, and the tie rings, which were wood, were also consumed. The arc in the slot welded the laminations together so that the stator core had to be taken down and the iron restacked, and between three and four tons of laminations replaced by new stock.

Two other cases that came under my notice were of 5000-kw. vertical units which burned out within ten minutes of each other. The cooling air for these units was drawn in at the top of the housing and discharged at the bottom, on top of the turbine casing. This made it very difficult to get at the fire. In one unit the burnout occurred right over the side where the throttle valve was located, so that the operating crew could not get to it to shut the steam off. The melted copper, iron, etc., from the burnt-off coils clogged the valve gear in the open position so that things were in excellent shape for a speed wreck, but fortunately the flame was so intense that it melted off the trip rod, from the emergency governor, thus releasing the throttle and allowing it to close.

These were old units which had seen hard service and, at the time they failed, were carrying heavy loads on account of another larger unit being out of service owing to a similar burnout. This latter unit failed at the end of a slot, doing some damage to the laminations as well as burning the ends of the coil on that end of the winding.

Another burnout that comes to mind was that of a large machine in which the trouble started at the end of one slot. The first indications of trouble were a few sparks for a short time before the actual burnout, which took the form of an explosion, shooting flame and smoke out of the air outlet on top of the generator. It required over two hours to put this fire out. In this instance the laminations were not injured, but all the coils were damaged and most of the tie rings were burned or cracked so that they had to be replaced. I believe that if this generator had been cut out at the first sign of fire, the trouble would have been localized and only one or possibly two coils damaged.

From these experiences I believe the surest way to localize the trouble is to kill the machine at the first sign of sparks or smoke. This may cause a shutdown for a short time, but that is better than burning out a machine, putting it out of service from two to eight weeks, depending on its size and the extent of the damage; besides, the cost of repairs may easily run up to several thousand dollars on large units.

Mr. Walker's suggestion for fire-fighting inlets or connections is an excellent one and should be adopted for all units. It appears to me that an effective scheme could be worked out by placing a ring of pipe around the ends of the stator just back of where the coils leave the slots, or in any suitable location where there is room, with sprinkler heads, such as are used with automatic sprinkler systems, at intervals of six or eight inches along the pipe so that they point in toward the coils; the melting point of the head to be, say, 50 deg. F. above the maximum allowable temperature of the generator, and the pipe line to be carried outside of the generator to a valve and connected to the water supply. There should be a drain opening between this valve and the sprinkler ring, which should be kept open so that any leakage of the main valve may be detected.

The pressure should not be kept on the sprinkler system all the time, as something might cause it to leak and damage the generator. In case there was a burnout or the attendant saw sparks or smoke coming from the generator, he could turn the water into the sprinkler system. If there was a fire at any point, one or more of the heads would be open and the water would be played on that point and not all over the machine as from a hose. If there was no fire serious enough to open the sprinkler heads, no water would reach the windings to cause damage. If the fire tended to spread around the armature, additional heads would open up to extinguish it.

This system could also be used in connection with carbon tetrachloride or carbon dioxide, as suggested by Mr. Walker, for fighting these fires, by connecting the system to tanks containing these chemicals under suitable pressure, instead of to a water supply. When using these chemicals, smaller-sized piping could be used to advantage.

I do not know whether this scheme has ever been used, but I see no reason why it would not work out satisfactorily, and the cost of installing the apparatus would be little compared to the expense of rebuilding a generator and the loss of service during the repairing.

The use of shutoff doors or dampers in the air inlets and outlets to the generator is another important detail, since with a turbo-generator with the field open, there is from a quarter of an hour to an hour in which the rotor will be turning and forcing air through the generator if these openings are not closed. These dampers should be controlled from the floor, where the engineer could reach them without leaving the throttle of the turbine. They should not be automatic in operation.

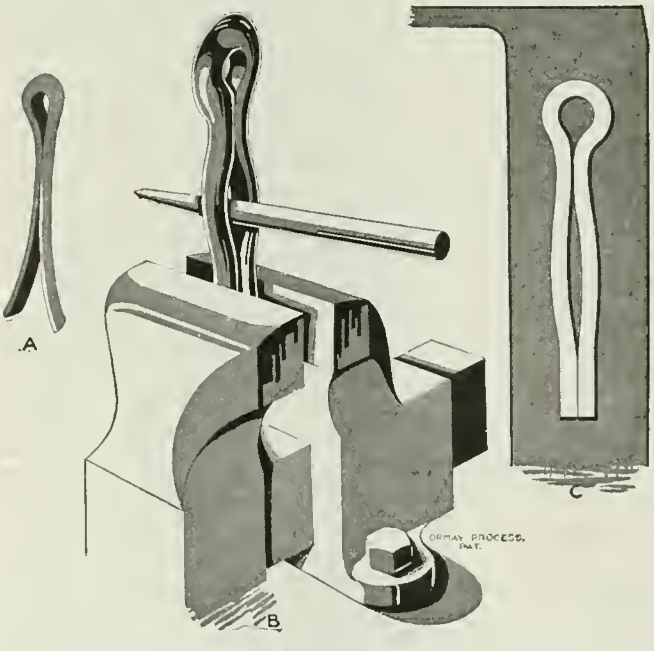
All of us who are in the business are interested in this subject, and I feel that it is very important to do what we can to help prevent these fires. They are not only a loss in profits to our companies, but are a waste, and at this time it behooves all of us to prevent such waste, whether of fuel, food, labor or material.

Claymont, Del. **Everett Palmer.**

Reusing a Cotter-Pin

The next time you try to replace a used cotter-pin that is spread at the end (as shown in the illustration at *A*), instead of trying to hammer the ends together, which cannot be done, try kink *B*. This produces a cotter of the shape shown at *C*, which is easily reëntered. This is a simple kink, and no doubt many readers will say, "Any fool oughter know that," but it has come to my notice that a lot of wiseheads do not make use of it, so I am passing it along. **C. H. Willey.**

Concord, N. H.

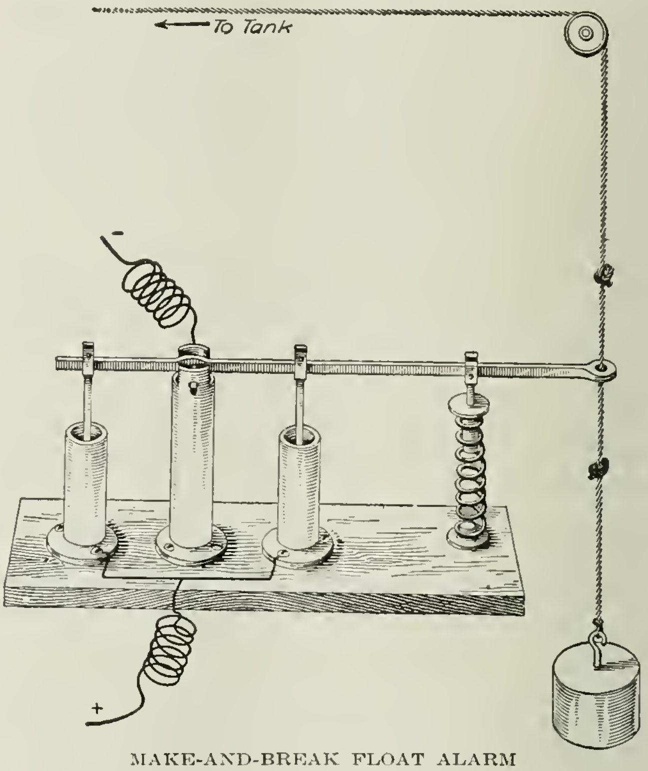


MAKING A COTTER PIN EASY TO ENTER

High and Low Water Alarm

I have made a successful high and low water alarm out of a couple of dashpots taken from old arc lamps and partly filled with mercury. A lever is pivoted, as shown in the illustration, so that when the long end is depressed or elevated by a knot on the float-cord passing through the eye at the end, contact will be made between the points on the lever and the mercury, completing the electric circuit, which lights a pilot lamp or rings a bell. The lever is held in a central or neutral position by the coiled spring until one of the knots forces it one way or the other, and the difference in the water level in the tank before an alarm is given depends on the distance between the knots.

Paxton, Ill. **S. R. Rodgers.**



MAKE-AND-BREAK FLOAT ALARM

Pump Strokes Irregular

In the plant where I am employed one 5½ x 3½ x 5-in. Worthington boiler-feed pump began giving trouble on one side. The right side would make the stroke all right, but the left would jerk and pound. At first I tried adjusting the valves, but this did no good, so I took the head off the water end and found that the night engineer in repacking the right side had put in four rings of packing instead of three, causing more friction on that side. So I added one ring to the left side and the trouble stopped.

The 14-in. by 30-ft. leather belt from a 75-hp. motor to an air compressor had been burned on one side, causing that side to stretch, and it flapped every time that part went over the motor pulley. I turned the belt over and the noise and disagreeable flapping stopped.

Provo, Utah. **O. W. Mann.**

Six new authorized United States battleships are designed to be of 41,500 tons, the largest battleships in the world.

Inquiries of General Interest

Use of Piston Valves on Compound Engines—For compound engines, why are piston valves frequently used for the high-pressure and flat slide valves used for the low-pressure cylinders? D. L.

For the high-pressure side, piston valves are preferable because they can be balanced and operated with little friction, and although repairs for making this type of valve steam-tight are more difficult than repairs to flat valves, tightness against valve leakage is of less importance on the high-pressure than on the low-pressure side of the engine.

Trapping Returns Discharged Below Boiler—Our heating system is supplied with steam at reduced pressure from boilers that carry high-pressure steam for power purposes. The returns from the heating system must be discharged about 10 ft. below the boiler. How can the return water be trapped to the boiler? J. E. H.

Place a return trap below the returns of the heating system and have this trap discharge to another return trap placed above the boiler for returning the condensate to the boiler. The most rapid operation will be obtained for the purpose by employing return traps whose receivers are vented to the atmosphere while filling.

Water-Hammer in Pump Suction Line—How can water-hammer be prevented in a pump suction pipe? A. H.

Water-hammer results from sudden checking of the velocity of the water at each reversal of the pump. It can be prevented by connecting an air chamber to the pump suction pipe in such a manner that when the column of water is stopped or checked by action of the pump, the direction of flow may continue past the pump suction chamber or valves to the air chamber. The energy of the moving column of water can thus be expended directly on the confined air; but an air chamber will be of little benefit if connected to the side or top of the suction pipe so the water passes under or at right angles to its connection.

Intrinsic or Internal Energy of Steam—What is the difference in signification of the terms total heat, intrinsic energy, internal energy and intrinsic heat of steam? A. D. B.

The term "total heat of steam" in any given state is understood to mean the amount of heat required to heat at constant pressure, a unit weight of water from the temperature of melting ice to the state under consideration. During the period of vaporization the volume of a pound of water is changed to the much larger volume of steam and the external work done in order to reach the state of the steam is called the "constant pressure external work." The terms intrinsic energy, internal energy and intrinsic heat are each used to signify the same thing, meaning the heat energy contained within the steam above 32 deg. F., and it is equal to the total heat less the constant-pressure external work.

Delta-Connected Transformer Banks Connected in Parallel—Would there be any objection to connecting two transformer banks in parallel, each bank being grouped in delta on both the primary and secondary? One bank consists of three 75-kw. units and the other bank of three 100-kw. units. D. C. A.

It would not be considered good practice to parallel two banks of transformers of different capacity such as indicated in the question. The chief objection to this practice is the difficulty that would be experienced to get the load to divide in the proper proportions between the two banks. To a certain extent this difficulty could be taken care of by connecting a resistance in series with the leads of the bank that has a tendency to take more than its share of the load. Even if the banks were the same capacity, it would not be good practice to operate them in parallel. If possible, each bank should supply a separate load.

Taking Gas- or Oil-Engine Suction-Stroke Diagrams—Diagrams made with the ordinary stiff spring necessary for use for indicating gas and oil engines afford little information of the action of the valves during the suction stroke. How can appropriate diagrams be obtained? A. E. R.

The events in the suction stroke must be obtained separately with a weak spring in the indicator. The spring should be protected from excessive pressure of the explosion stroke by inserting a suitable stop to prevent undue compression of the spring. For that purpose a distance piece may be made of a small brass tube slipped over the piston rod of the indicator or, for an indicator with an inside spring, the distance piece may consist of a thin brass tube that will freely pass over the outside of the spring and inside of the indicator cylinder while resting on the top of the piston.

Scale-Forming Impurities in Feed Waters—What are the usual scale-forming impurities in boiler feed waters? C. N. D.

Those most often present and in largest quantities are:

Calcium carbonate (lime), chemical formula	$CaCO_3$
Magnesium carbonate, chemical formula	$MgCO_3$
Calcium sulphate, chemical formula	$CaSO_4$
Magnesium sulphate, chemical formula	$MgSO_4$

The impurities less frequently found and usually in small amounts are:

Iron carbonate, chemical formula	Fe_2CO_3
Calcium chloride, chemical formula	$CaCl_2$
Magnesium chloride, chemical formula	$MgCl_2$
Potassium chloride, chemical formula	KCl
Sodium chloride, chemical formula	$NaCl$

Some iron oxides, calcium phosphate, silica and organic matter also may be found, though usually in small quantities.

Effect of Clearance on Air Compressor—What effect has cylinder clearance on the capacity and power required by an air compressor? S. E. M.

In single-stage compression, clearance reduces the volumetric efficiency or ratio of the volume of free air, actually admitted and compressed in the intake cylinder, to the volume of piston displacement. The percentage in reduction of capacity is greater than the percentage of cylinder clearance, as the piston must travel back a larger percentage of the return stroke before the air previously compressed into the clearance spaces has expanded to atmospheric pressure, permitting the free air supply to flow into the cylinder. Since the volume which the expanded clearance air occupies increases as the pressure increases, the loss in capacity by clearance is directly proportional to the pressure. The loss of volumetric efficiency due to clearance is less for two-stage than for single-stage compression because, for given capacity, the low-pressure cylinder of two-stage compressors is practically of the same size and has the same percentage of clearance as the cylinder of a single-stage compressor, and the terminal pressure of the two-stage machine is much lower with less expansion of the compressed clearance air back into the cylinder volume. The work required for compressing the clearance air to receiver pressure in expanding back to atmospheric pressure helps to move the piston on the return stroke and as the loss of heat during expansion is negligible there is practically no loss of power from clearance excepting that its presence increases the size of compressor required to deliver a stated amount of air, thereby requiring more power for its operation.

Notes on the Operation of Submarine Diesel Engines*

By LIEUT. F. C. SHERMAN, U.S.N.

The following notes have been made as the result of practical experience in operating submarine Diesel engines of the two-stroke-cycle Nürnberg type of New London Ship and Engine Co. manufacture. They are particularly applicable to that engine, but it is felt that some of the ideas evolved may be adaptable to engines of other types when similar troubles have been experienced.

IN spite of the widespread reports of unreliability of submarine Diesel engines of the past few years, the writer has always maintained that every effort should be made to make the material operate satisfactorily before condemning it as unsatisfactory and unreliable. In many cases further investigation has shown that inexperienced personnel are to blame and not the long-suffering and almost always blamed material.

In the type of engine upon which this discussion is based, the crank case is totally inclosed and the oil from the lubricating system, after cooling the piston heads, is drained into the crank case, from which it runs into the settling tank and is used over again. The scavenger air for the working cylinders is compressed in a scavenger cylinder in tandem with the working cylinder, and the piston is of the stepped type, the lower step working in the scavenger cylinder and compressing the scavenger air which is forced into a housing around the scavenger cylinder and above the crank case. The scavenger cylinder makes a joint between the crank case and the scavenger housing.

Crank-Case Explosions

Now, in every case of crank-case explosions it was found that there was a leak from the scavenger housing to the crank case. This joint was packed with soft packing and proved to be very difficult to keep tight, due to the scavenger cylinder holding-down bolts working loose from continual shock. But in every case of crank-case explosion, a leak of scavenger air to the crank case was found, and when it was corrected the explosions stopped. The permanent care taken following this discovery was to test the scavenger housing at frequent intervals for tightness with air pressure and to examine frequently the scavenger cylinder holding-down bolts and to keep them set up tight every time they came loose. These tests were made about once a month, and following this care, practically all crank-case explosions and their destructive results were eliminated.

Another remedy adopted, not as a cure but to reduce the effect of a crank-case explosion, was to install a vent to the crank case. The crank case is totally inclosed only to retain the oil used in the lubricating system and prevent its being splashed about in the engine room. The result was that when a crank-case explosion occurred the gas had no place to escape without wrecking something, blowing off the crank-case doors or housing. To prevent this, a 2½-in. pipe was led from one end of the crank-case housing and left entirely open. The main purpose of the pipe was to furnish an opening to the crank case to allow the expanding gases of the explosion to get out without blowing something out.

Another feature of the leak in the scavenger housing was found to be that the scavenger-housing temperature increased unduly, especially when running at higher powers. This undue rise of temperature probably resulted from slight burning of the oil vapor around the leak causing an increase of the temperature without, however, causing an explosion. A correction of the air leak always resulted in a decrease of scavenger-housing temperatures. These leaks from the scavenger housing, it must be understood, were not sufficient to cause trouble from drop in scavenger-air pressure and would ordinarily not be expected to give any trouble.

Closely allied with the crank-case explosions, but of an entirely different nature, were scavenger-housing explosions. These were found to be due to two causes; namely, presence of a superfluity of oil in scavenger housing and leaky or defective scavenger valves. If there was too much oil in the scavenger air and the scavenger valve to the working cylinder remained open an instant too long or leaked after it was closed, the compression temperature or flame from the working cylinder would be transmitted to the scavenger housing and set off the oil and vapor in that chamber, resulting in an explosion liable to wreck the housing, as relief valves fitted there were never efficient in quickly releasing the excessive pressure formed. The remedy for this form of explosion was to keep excessive oil out of the scavenger housing through drains fitted at the bottom and to keep the scavenger valves to the working cylinders functioning properly.

Piston and Cylinder Troubles

Cracked piston heads, cracked cylinders, cracked pistons and piston seizures are almost all traceable to defective cooling of the piston head. On the particular type of engine in question, the pistons were cooled by lubricating oil forced up from the lubricating system through the connecting-rod and wristpin and then up through a pipe leading to the hollow piston head and thence down on the opposite side through a drain pipe to the crank case, whence it drains by gravity to the settling tanks.

The most frequent cause of defective cooling of the piston heads was the presence of salt water in the lubricating oil which remained in the piston head owing to the location of cooling-water inlet and outlet. Due to the temperature to which the oil was subjected, the water would quickly evaporate, leaving a salt deposit in the oil which was black in color, giving the appearance of carbon. For a long time this deposit was thought to be carbon, on account of its color, but an analysis showed it to be over 90 per cent. salt. This salt would form a black, gummy mass and would soon collect in the piston heads and the pipes leading to them and result in decreasing or blocking altogether the supply of cooling oil to the piston heads, which would instantaneously get hot and either crack or seize, or heat would travel to the cylinder or piston itself, resulting in cracking the cylinder with its cooling water outside or the piston seizing and cracking.

Obviously, the remedy for this is to keep salt water out of the oil. However, with an engine using salt water for its cylinder-cooling and oil-cooling medium, this is not as easy to do as it sounds; but it can be done if proper care is exercised. On the vessel on which the writer served it was never completely accomplished until the circulating water pumps were removed from over the crank case where water leaking slightly past the plungers and stuffing-boxes found its way into the crank case and there mixed with the oil.

Troubles from Oil Coolers

Another frequent source of trouble were the oil coolers, where the oil is cooled by circulating water before being again used in the engine system. The oil passed through nests of tubes surrounded by cooling water, and trouble was experienced in preventing tubes from pitting through and gaskets from leaking. Whereas the oil pressure when the engine was running was greater than the water pressure, the leak would become effective when the engine was shut down and the lubricating-oil pumps stopped. Water would

---

*Abstract from the "Journal of the American Society of Naval Engineers."

then leak in and cause trouble on the next run of the engine. Another source of leaks was from slight cracks in cylinders, sometimes quite imperceptible to the eye when the cylinder was cold, but allowing slight leaks of cooling water to crank case when warm. All these leaks, wherever they may be, must be prevented to insure proper cooling of piston heads and to prevent troubles ensuing from this source.

WRISTPIN TROUBLES

Wristpin troubles, in brief, are due to insufficient lubrication, insufficient clearance, undue wear on bushing or pin and heating resulting from hot piston or piston head. The trouble due to insufficient lubrication is sometimes traceable to the salt water in the oil. In other cases, however, it may be due to improper grooving of the wristpin bushing or bearing surface. This subject must be studied in connection with the approved forms of oil grooves for bearings, and steps taken to insure that the oil is being properly distributed on the wristpin bearing.

On engines with forced-lubrication pumps operating from the main engine shaft, hot wristpins frequently develop on first starting up an engine. This is probably caused by lack of lubricating oil in the wristpin bearings, the highest part of the system, when the engine is first turned over. This can be prevented on engines with an independent lubricating pump by starting up the auxiliary lubricating pump several minutes before attempting to turn over the main engines and running it long enough to insure getting lubricating oil to all parts of the system. This should always be done before starting up, as frequently wristpins will run hot and wipe in the few minutes before oil from the attached pumps can get to them.

Insufficient clearance on wristpin bushings sometimes results in not allowing sufficient lubricating oil to form a good film on the bearing and causes wiping or heating of the wristpin. Good practice is to allow about 0.002 in. vertical clearance between the pin and bushing and about 0.006 to 0.008 in. clearance on the sides. This additional side clearance gives no more play in the bearing, as the pressure is always vertical, but gives the oil a better chance to circulate in the bearing and form the oil film or lubrication.

Undue wear on wristpin bushings results in loss of lubricating oil from the bearing due to leakage, and also in loss of compression in the cylinders from the dropping down of the pistons. Consequently, anything that can be done to prevent undue wear on the wristpin bushings is important. In addition, loss of compression in the cylinders causes inefficient combustion of the fuel, reducing the economy of the engine, and necessitates frequent overhaul and insertion of liners under connecting-rods to increase compression, or frequent renewal of wristpin bushings.

The bushings should be of phosphor bronze, of as tough and durable a composition as possible. The wristpins are of steel, hardened on their wearing surface by either the bone or cyanide process. The wristpins furnished us originally were bored out from one end only and that end plugged with a threaded brass plug. We found that the pins would take a more uniform heat and better hardening if the pins before hardening were bored clear through and both ends plugged with the threaded brass plugs. This was a slightly more costly process, but resulted in much better pins, and is recommended for all wristpins for Diesel engines.

AIR-COMPRESSOR TROUBLES

Diesel engine air-compressor troubles comprise valve trouble, cooler leaks and explosions. They are due to the high temperatures created when the air is compressed in two or more stages from atmospheric pressure to approximately 1000 lb. per sq.in. In the type of engine mentioned at the beginning of this paper, the compressor was designed to take its suction from the scavenger-air housing, and it was then compressed in two stages in tandem to 800 lb. to 1000 lb. per sq.in. This air was cooled from each stage in a cooler consisting of nests of small, straight tubes around which circulated cooling water. The air from the second-stage cooler passes to the spray-air bottle which acts as a reservoir on the way to the spray-air line of the engine. It will be seen that when the two-stage air compressor takes its suction from the scavenger housing containing air at 7 lb. pressure (above atmosphere) it virtually makes a three-stage compression. On our engine, however, there was always so much oil in the scavenger housing that it was considered dangerous to compress air containing so much oil and subject it to the temperatures reached, and in practice it gave considerable trouble. So the suction to the scavenger housing was disconnected and a suction direct to the atmosphere substituted which gave a straight two-stage compression from atmospheric pressure to 1000 lb. per sq.in. This worked much more satisfactorily as regards presence of oily vapor in the compressed air and occurrence of cooler explosions.

A common practice in Diesel-engine design seems to be to have a restriction in the spray-air line between the reservoir and the engine. The only object of this, that I have been able to discover, is to enable a higher pressure to be carried in the reservoir than is needed on the spray-air system, so as to build up a reserve for starting after the engine has been shut down. If this is its purpose, it never was successful for us, and only resulted in reducing the amount of spray air we were able to get through to the fuel valves. Furthermore, it would frequently clog up and catch dirt and oil to further reduce the opening, so that in general it was more of a nuisance than anything else. Acting on this belief, the restriction on the spray air was removed entirely and much better results in every way were obtained. Whereas, before poor fuel combustion had been obtained when carrying 800 lb. to 900 lb. pressure on the spray air, after removing the restriction perfect combustion was obtained with as low as 550 lb. to 600 lb. pressure on the spray air.

Another point in regard to air-compressor trouble is cylinder lubrication. The principal danger is too much lubrication, allowing oil to be carried into the compressed air and causing high temperatures or explosions from burning or combustion of the oil vapor. The best practice is to eliminate direct cylinder lubrication entirely and depend on the moisture and oily vapor in the engine-room atmosphere to furnish sufficient lubrication. In practice this worked very well for us, and we had no trouble from lubrication while using no oil whatsoever directly on the air compressors.

VALVE TROUBLES

The principal valve trouble which we experienced was due to the valve springs losing their temper after a few hours' running, due to the high temperatures of the uncooled air to which they were subjected. The second-stage suction valve was the principal source of trouble, and when its spring gave out it would leak, allowing second-stage pressure to back up in the first-stage receiver and increase the work on the first stage and in general raise hob. Another source of valve trouble was the gradual collection of carbon deposits on the valve seats due to the presence of oil in the air and causing the valves to leak.

Cutting off the oil used for cylinder lubrication helped both troubles. But the greatest assistance to correct these faults was a water cup installed on the first-stage air suction and set to feed a small quantity of fresh water into the compressor with the air. This water cup was simply a large oil cup arranged for drop feed, filled with fresh water instead of oil. A fairly rapid feed was set on it, about two to four drops per second, and this water was dropped through the top of the air-suction pipe and drawn into the compressor with the air. The action of this fresh water was found to be as follows: It helped to lubricate the valves and cylinder walls and prevented the deposit of carbon. The high temperature almost immediately turned it into steam, absorbing some of the heat without rise of temperature in the form of latent heat, and thus keeping down the temperatures developed due to compression. In addition the steam kept the carbon from collecting and gumming up the valves, and the reduced temperatures resulting prevented the springs from losing their temper. This fresh-water cup was a fine thing, and I strongly advise other Diesel-engine operators to try it on their air compressors.

Cooler leaks were probably caused by high temperatures and possibly some electrolytic action on the tubes. The installation of the water cups kept down the temperatures and also kept carbon and oil from collecting in the coolers and restricting the heat transference. To prevent electrolytic action the outside of the copper tubes was tinned and small zincs were placed in the cooler. These precautions eliminated almost all of our air-compressor troubles. In addition all clearances were kept down to a minimum, about 1-64 in. on both stages.

AUXILIARIES

The principal troubles experienced with auxiliaries were with those geared to the main shaft. These pumps were the reciprocating type and comprised a fuel-feed pump, a lubricating-oil pump and a circulating-water pump, all driven by one large crosshead operated by a crankshaft geared to the mainshaft. The first trouble experienced was with the fuel-oil supply pump, which leaked, in spite of efforts to keep it tight, a small amount of fuel oil into the crank case. After mixing with the lubricating oil this caused rapid deterioration of the latter for lubricating purposes, as well as scavenger and crank-case explosions from its low flash point and volatility. To obviate this trouble the fuel-pump was removed and a gravity fuel feed substituted, the gravity fuel tank being supplied by a small motor-driven rotary pump, secured to the bulkhead. This removed all possibility of getting fuel oil into the lubricating oil and prevented recurrence of its evils.

The lubricating-oil and circulating-water pumps were the next to give trouble. They were high-speed reciprocating pumps, and it was almost impossible to keep salt water from leaking from the circulating-water pump and finding its way to the crank case and, ultimately mixing with the lubricating oil, causing all the troubles already enumerated. In addition, mechanical difficulties with these reciprocating pumps caused by momentary high pressures when the pump became air-bound or through defective valve action, resulted in frequent stripping of gears and breaking of pump crankshafts. These breakdowns finally became so frequent that independent motor-driven rotary-type pumps were installed for both lubricating oil and circulating water. The reciprocating-pump connecting-rod was disconnected and lashed clear, and the salt-water connections were blank-flanged to prevent any possibility of salt water leaks, and these pumps were not used but were kept available for connecting up in case of failure of the independent pumps. In nearly two years of operating they were never needed, the independent pumps operating entirely satisfactorily. As a result of this, we became strong advocates of independent auxiliaries for submarine Diesel engines.

The fuel-measuring pumps were of the plunger type, driven by an eccentric off the mainshaft. The regulation was by means of the suction valves being held open for a part of the discharge stroke to control the quantity of fuel oil discharged to the fuel valves. This regulation was made by the operator through a handwheel controlling the rocker arm operating the valves. These pumps gave very little trouble except from wear, and it was necessary to renew the plungers and barrels about every six months to a year on this account. The plungers were required to fit the barrels very closely on account of loss of pressure through leakage past the plungers. Aside from this amount of wear these pumps gave no trouble, and the method of control was entirely satisfactory.

Inspection of Governors

Ninety per cent. of flywheel accidents are due to a failure of the governor mechanism, therefore the following points should be carefully observed: (a) That the governor mechanism works freely and does not stick in any way; (b) that the governor belt is of ample strength, and does not slip, due to oil or other cause (do not use an old oil-soaked belt); (c) that the governor pulley or gears are tight on their shafts.

Engines have run away due to a key dropping out of the bevel gear on the vertical spindle of the governor, or to the loosening of a setscrew on the governor pulley.

Do not under any circumstances remove or set back the safety-cams on a releasing valve gear or block the governor, so that the governor stop is made inoperative.

Always remove the stop-pin from the governor stand immediately after starting up. This precaution is so often forgotten or neglected that the adoption of a simple semi-automatic device is strongly recommended. It may consist of a small lever pivoted to the governor standard and so balanced that it drops out of place automatically when the momentum of the balls becomes sufficient to lift the governor-rod off it.

A refinement of the same idea, which obviates the necessity of the engineer holding the "pin" in place when shutting down, or else of lifting the governor rod up on the "pin" after the engine has stopped, is shown. This appeared in *Power and the Engineer* for Feb. 2, 1909, from which the following description is quoted:

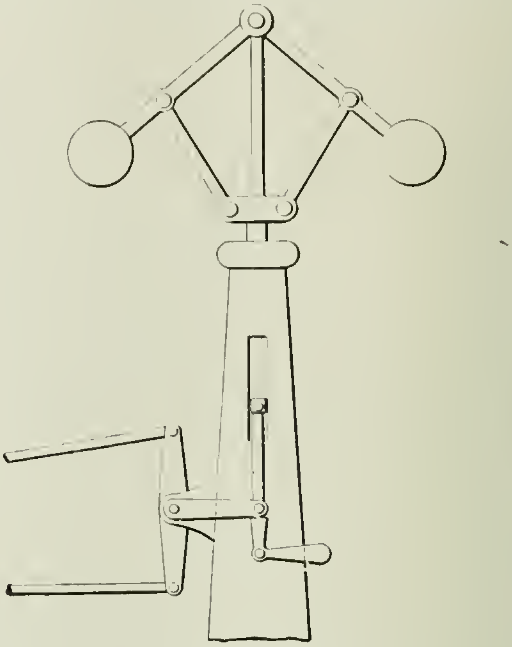

FIG. 1. HANDY AND SAFE STOP PIN

> The device is simple and any engineer can make and attach one himself. The illustration shows three positions. The first is that in which the stop is placed just after closing the throttle and before the speed is much reduced. It will be noted that the fork is not directly under the end of the rod that comes down from the collar. As this rod drops the fork centers and allows the small dog to drop, as shown in the second view. When the engine is again brought up to speed, the rod rises, and the fork is pulled over to one side out of the way by the weighted end as shown in the third view. This leaves a clear path for the rod should anything happen to stop the governor.

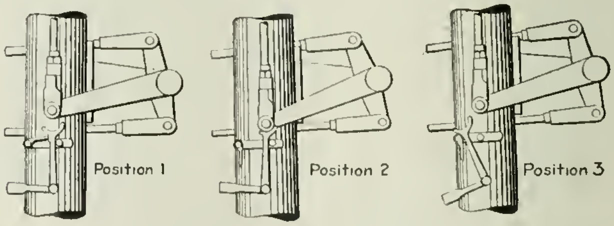

FIG. 2. MODIFIED FORM OF SAFETY STOP PIN

Never put heavy grease in the oil pot of the governor.

Examine all screws at frequent intervals, especially those in the cutoff and safety cams, to make sure that they do not work loose. The working loose of the lower screw in a cutoff cam some time ago was the cause of a flywheel wreck.

Be sure the stop collar of the governor is in such position that steam is cut off when the balls drop near the low limit. Also be sure that when the governor balls are at the upper limit, the knockoff cams shut off all the steam and do not pass clear under the crab claw and get caught. This was the cause of a flywheel wreck not long ago.—*National Safety Council.*

Plant Records and the Importance of Keeping Them

The following is from a lecture prepared by Prof. L. P. Breckenridge as part of his fuel conservation work for the Fuel Administration:

Unless records are kept, it will be impossible to know whether the boiler plant is operating at a good or a bad economy. Well-kept records are valuable, and reference to them from month to month, or even from year to year, frequently reveals some unsuspected and wasteful method of operation or shows the value of one kind of coal as compared with another. Where records are kept, it gives the fireman a chance to watch the effect of different methods of running; and this of itself will often lead to economy sufficient to repay fully any cost of installing suitable facilities for keeping the records as well as the slight cost of recording the necessary daily observations. When it is known that records are kept, the operating staff begin to take more interest in securing good records.

RECORDS FOR THE SMALL PLANT

It might be well to classify steam-power plants arbitrarily according to their size, and the writer would suggest the following: The small plant, 10 to 100 hp.; the medium plant, 100 to 500 hp.; the large plant, 500 to 5000 hp.; the commercial plant, 5000 to 300,000 hp.

It is in the small plants that is usually found the greatest waste of both coal and steam. Frequently, in these plants as much as ten pounds of coal per hour is used to produce one horsepower. This is much too large an amount. There may be conditions of operation that would sometimes justify this large consumption, but such cases need not be many, and the coal consumed to produce one horsepower should not exceed five pounds per hour even for the small plant. For the small plant the following daily records should be kept in connection with the operation of the boiler: (a) The kind and size of coal used; (b) the steam pressure; (c) the temperature of the feed water; (d) the weight of coal burned; (e) the weight of water evaporated; (f) the weight of ash.

In the medium plant, in addition to the foregoing records, the following should be kept: (g) The temperature of the escaping gases; (h) the temperature of the boiler room; (i) the composition of the escaping gases; (j) the draft pressure in furnace and base of stack; (k) the quality of the steam; (l) the heating value of the coal.

It is, of course, necessary to have the dimensions of boilers and furnaces in order to make the necessary calculations for which these records are kept.

For the large plant and for the commercial plant a few additional records are desirable, but for these plants the records as now usually kept are quite complete, and for many plants the records are continuously recorded.

The coal consumption per horsepower per hour in a medium plant varies greatly, but it is probable that if a large number of plants were taken as they are running today it would be found that at least five pounds of coal was used for one horsepower, when it ought easily to be possible to reduce this to three pounds per horsepower per hour.

In the large plant and in the commercial plant the possibilities for economy increase with the size of the plant; here the coal consumption per hour should never exceed three pounds per horsepower, should usually be well under two pounds, and in some plants operating under best conditions the consumption may soon be as low as 1¼ pounds per horsepower per hour.

HOW RECORDS SHOULD BE OBTAINED

It is not within the scope of this lecture to explain in detail how the specified records should be obtained. There are available numerous excellent laboratory manuals giving full instructions for the installation and use of instruments necessary or useful in connection with any plan for keeping records. It should, however, be observed that the records suggested for this small plant are very simple and may easily be obtained; for example, the steam pressure is read from the gage on the boiler, a special thermometer is procurable which may be screwed into a fitting in the feed line, or a mercury well with a simple glass thermometer may easily be arranged for the purpose of reading the temperature of the feed water. The weight of coal and ash will require a pair of scales, but a record of wheelbarrow loads properly trimmed off to a known weight is better than no record at all. The weight of water fed to the boiler can best be determined by installing a meter on the feed line. Meters are made for hot or cold water. They are not always accurate, but are easily checked up once or twice a year and for comparative purposes are quite satisfactory. With this simple equipment much valuable information may be obtained. It has been suggested already that consumers of coal must know how it is used, that in the future extreme waste may be prohibited.

HOW TO USE THE RECORDS

There are two ways of making good use of the records: (a) Compare your results with the best records obtained with similar equipment elsewhere; (b) compare your daily, weekly or monthly records with one another, with the object of increasing economy or reducing cost of operation. The records should be inspected by someone whose duty it is to look after "waste." If a graphic chart is made from the records, it will often show at once the influence of some unseen leak, the defect of equipment by breakage or improper setting, poor method of operation or change of coal. Corrections may then be made before the "waste" has continued a month or more. Someone in charge of power-plant operation must submit a monthly report to the general manager or owner, and this report must be given some interest and attention. The fireman must be shown his records from month to month and encouraged to fire in accordance with the best-known methods.

Any attempt to reach a conclusion as to what is a satisfactory performance leads to endless discussion. This is natural because of the commercial importance which necessarily must be considered as a part of the problem. When a power plant is manufacturing electrical energy for distribution and sale, the cost of the coal used may constitute 60 per cent. or more of the entire cost of producing its product. If, on the other hand, a power plant is generating 300 hp. for the manufacture of boots and shoes, it may be found that the cost of coal required for power generation and heating is less than 1 per cent. of the cost of production, so that frequently manufacturers have not given much attention to their power-plant operation.

The table is presented with the hope that it may be some indication of what economies may reasonably be expected in the operation of several types of power and heating plant boilers both for the production of steam and the generation of power.

REASONABLE ECONOMIC PERFORMANCE

(Stationary Steam Plants)

Type of Plant	Efficiency of Boiler and Furnace Per Cent.	Coal per Hour, Lb. Per Kw.
1. Central Stations:		
(a) Large, 10,000 kw. and up... .	70–76	3–2
(b) Small, 2,000–10,000 kw......	68–74	4–2½
2. Manufacturing power plants:		Per I.Hp.
(a) Small plants up to 100 hp.....	60–70	8–5
(b) Medium plants 100 500 hp ..	68–72	5–3
(c) Large plants 500–2,000 hp...	68–74	4–2½
3. Heating plants:		Per Boiler Hp.
(a) Central 1,000 hp. and up ...	68–74	4–3
(b) Office buildings, public bldgs.	50–70	6–3
(c) Residences	50–65	..

Even better results than those indicated are now frequently found, but it is a fair question if plants should be allowed to operate under conditions which give efficiencies below the low points indicated.

In order to standardize the form of report submitted by engineers and also to suggest approved methods of testing the different kinds of equipment, the American Society of Mechanical Engineers appointed in 1909 a Power Test Committee. This committee has prepared the "Power Test Code" of the A. S. M. E. This code was printed in 1915 and is available. It is being revised and extended and will soon be in excellent form for general use for all engineers and manufacturers. It is hoped that all important tests will conform to this code. In it will be found not only forms and methods, but also much detailed information as to the installation and use of the various instruments of precision employed in connection with tests of all kinds. All students of engineering should become familiar with this "Code of Rules for Conducting Performance Tests of Power Plant Apparatus."

The Fuel Administration's Regulations as to Clean Coal

The order of the United States Fuel Administration regarding the production of clean coal went into effect Mar. 11, 1918. According to its terms, district representatives of the Fuel Administration are authorized to appoint inspectors in sufficient numbers to carry out the provisions of the order.

The duty of each inspector is to make frequent and thorough inspections of the coal mined in the particular territory to which he is assigned and to observe the conditions under which it is mined and produced. If he finds the coal in any part of a mine to be naturally of such character as to be unfit for market, the district representative may order mining suspended in that part of the mine until proper cleaning methods are adopted; but work cannot be so suspended if it endangers life or if it may result in flooding or squeezing.

The inspector must make a daily report to the district representative of the Fuel Administration, stating the number of mines inspected, the condition of the coal as loaded, the methods used to prepare and clean the coal, and whether, in his judgment, the product being shipped to market is a well-prepared and merchantable product.

If an inspector finds coal loaded in railroad cars at the mines and is not of the opinion that it is properly prepared, he may condemn it. But he must immediately notify the district representative and the operator by wire or in person and in writing, giving the car numbers and initials of any and all cars so rejected and stating the reasons for his action.

If the district representative approves the inspector's report, he must notify the operator at once. If the operator does not unload the rejected coal at once and reprepare it, the consignee is permitted to deduct 50 cents per ton from the authorized price for the grade of coal in the car; but the consignee, after examining the coal, may at his option pay, and the operator may receive, the full authorized price.

Each invoice covering the sale of condemned coal must bear a notation to the effect that the reduced price is fixed by the United States Fuel Administration as a penalty for improper preparation. The operator must immediately report to the United States Fuel Administration at Washington and to the district representative how he disposed of the condemned car or cars of coal and a copy of the invoice must accompany his report.

The terms, conditions and validity of existing contracts are not affected or altered by the clean-coal regulations; but all new contracts are subject to the provisions of the order.

The object of the order, of course, is to discourage the marketing of slate, bone and other impurities at the same price as clean coal. But the regulations apparently contain a "joker." For, after stating that the consignee may purchase the condemned coal at a reduction of 50 cents a ton, they add:

> . . . provided, however, the consignee, after examining the coal, may, at his option, pay and the operator receive the full authorized price.

Commenting on this provision, a writer in *Fecony* pertinently remarks:

> Why were such pains taken to permit a producer of poor coal, a waster of our National resources, to receive "the full authorized price?" The coal market is a "sellers' market," and it will be for some time to come. Every coal producer knows that most manufacturers have very small reserves, and that once a car of coal is on a consumer's side-track, it is ten to one that he will not reject the coal, especially as he has probably been counting on the arrival of that car. How easy it will be to insist on "the full authorized price." Even if the original consignee is in a position to reject a particular car, every coal producer knows it is a safe bet that there is at least one near-by plant that will be glad to take anything to tide over a temporary shortage at any price. What chance is there of an operator actually suffering any penalty for poor preparation, and besides how many of the seven or eight million carloads shipped to manufacturers and retail dealers are going to be "inspected"?
>
> Careful provision is made in the order for notifying almost everybody by telegram of the condemnation of a car, except the consignee. If the Fuel Administration is really interested in the maximum manufacturing efficiency, why wasn't provision made for prompt notice to the consumer that a car of condemned coal is on the way? Is the operator going to do it voluntarily? Is he going to rush off by special-delivery mail the invoice, showing that the car contains condemned coal, so that the consumer can make other arrangements for coal to take its place?

Carbocoal

A paper prepared by Charles T. Malcolmson, president of the Malcolmson Briquette Engineering Co., Chicago, for presentation at the Colorado meeting of the American Institute of Mechanical Engineers in September of this year, describes a process for the manufacture of smokeless fuel from high-volatile coals and for the recovery and refinement of the coal-tar products derived therefrom. The products of the process are a fuel called carbocoal, which, for convenience in handling, is prepared in briquet form; a yield of tar more than double that obtained in the ordinary byproduct coking process; ammonium sulphate in excess of that normally recovered in the ordinary byproduct coking process; and gas in amount approximately 9000 cu.ft. per ton of coal carbonized, which is at present used in the process.

The raw coal, after being crushed, is first distilled at a temperature of 850 to 900 deg. F., and the volatile contents are thereby reduced to the desired point. The result of this first distillation is a large yield of gas and tar and a product rich in carbon, termed semi-carbocoal. This product is mixed with a certain proportion of pitch obtained from the tar produced in the process, and the mixture briquetted. The briquets are then subjected to an additional distillation at a temperature of approximately 1800 deg. F., resulting in the production of carbocoal, the recovery of additional tar and gas, and a substantial yield of ammonium sulphate.

The carbocoal represents more than 72 per cent. of the weight of the raw coal, the exact percentage depending upon the volatile content of the latter. It is dense, dustless, uniform in size and quality, and can be handled and transported long distances without disintegration. It is grayish black in color, slightly resembling coke, but in density more nearly approaches anthracite. It is applicable to about the same kind of service as anthracite would be, one of its most valuable characteristics being that of smokelessness.

Uruguay Requires Use of Metric Units

One of the measures recently adopted by the Government of Uruguay, says *Commerce Reports*, makes the use of metric units in all trade transactions obligatory. A decree of Feb. 8 provides that merchants dealing in articles susceptible of being sold by weight or measure must adhere to the metric system and forbids them to sell by the piece or package or for a fixed sum of money, even when the customer so demands. Where merchandise is sold in sealed wrapping, cans, boxes, packages, bottles, demijohns, etc., the net contents or weight contained must be indicated on the wrapping in an easily visible manner. In books of account and invoices the weight or measure of merchandise sold must be stated. Merchants dealing in articles of prime necessity must post in their places of business the daily prices of such articles, stating the weight or measure.

It is very advisable to have more than one way of getting out of a boiler or engine room, even if one of them is not very handy.—*Marine Engineering.*

Power for the Nitro Powder Plant

The United States Government has not only entered into a contract with the Virginian Power Co. of Charleston, W. Va., to furnish power from its plant at Cabin Creek Junction, near that city, for the mammoth powder plant at Nitro, about 16 miles below Charleston, but has arranged for an interchange of current between the Virginian Co. and the Appalachian power concerns, the two largest power companies in the state.

To insure adequate current for the Government needs at Nitro, the producing capacity of the Virginian's plant is being trebled, and an expenditure said to be in the neighborhood of $1,000,000 will be necessary to cover all the improvements. Some time ago, the company actually began to install new machinery sufficient to double the capacity of the plant, but owing to the condition of the money market was unable to finance the completion of such improvements. Not long ago officers of the company presented to the Government the proposition of assisting in the enlargement of facilities without waiting for an easier money market. It is believed that the negotiations led to the contract that has been made between the Government and the Virginian company.

General Manager H. G. Scott has made this statement in connection with the new arrangement:

> It was announced to the Public Service Commission that the Virginian Power Co. has concluded a contract with the United States Government whereunder all the electric-power requirements of the power plant at Nitro will be taken care of by the Virginian Power Co. from its plant at Cabin Creek Junction.
>
> The contract provides that two circuits over two separate and distinct routes shall be constructed for the service of the powder plant only. The contract was so arranged by the Government as to provide for the full power requirements of the coal mines. The equipment now being installed at the company's plant is practically the same which the company has had ordered for about a year. This contract, however, provides not only for the completion of the installation, but that it shall be done immediately.
>
> It is planned to physically connect the power systems of both the Virginian Power Co. and the Appalachian Power Co. in order that these companies may interchange power for the purpose of sustaining the service in the most continuous and economical manner. This plan has been successfully carried out in California, where all the larger companies are interconnected.

Injury by Defectively Repaired Boiler

"A steam boiler is inherently dangerous, and one who repairs it owes a duty of proper care to avoid injury, not only to the property and employees of the purchaser, but to all persons who may be thereby subjected to injury, and to that end must perform his work properly." This language was lately used by the Appellate Division of the New York Supreme Court in the recent case of Rosenfeld vs. Albert Smith & Son, Inc., et al.; 168 New York Supplement, 214. The court affirms judgment for death of a youth who was standing near a boiler in the power plant of a hotel building when the rear boiler head bulged out and steam escaped in fatal volume.

A hotel company holding a lease on part of the building contracted with the appellant, Albert Smith & Son, for the replacing by the latter of tubes in two boilers, the work to be done in a first-class manner and to be "perfectly tight." In the process of doing the work, appellant's employees used shims 1/32 in. thick to fill the spaces between the ends of the tubes and the inner surface of the boiler heads. But the shims were not continued all the way around each tube, being tapered or scarfed at the ends and extending only about halfway around the tubes. Apparently it was not claimed that there was any negligence in failing to bead the tubes, instead of using shims, but plaintiff offered evidence tending to show that the shims should have been extended all the way around, and that they should have projected beyond the boiler heads instead of being flush as they were, and should have been flared with the tube ends so that they would tend to resist the pressure from within and prevent the bulging out of the boiler heads. It was found after the accident that the rear boiler head had bulged out on a vertical line three-fourths of an inch, resulting in 27 tubes in the center dropping inside the boiler and the other tubes being left barely holding.

The assistant engineer testified that the gage registered only 97 lb. a few minutes before the accident, although after the tubes had been installed the boiler had been subjected to hydrostatic tests of 160 and 190 pounds.

Appellant contended in the suit that, even if it were conceded that the boiler was negligently repaired by its workmen, still the engineer in charge of the plant had tested and accepted the boiler as being in satisfactory condition. But the court decided that, under the facts established, it did not appear that the engineer was authorized to waive any defects in the boiler, and that the only bearing the tests had was as evidence on the question whether the boiler was skillfully repaired or not.

The court further held that the jury's finding that the work was negligently performed was partly sustained by testimony showing that on the first test 29 tubes were found to be leaking and sweating, and other testimony tending to show that the final test, made after further repair, was not properly or sufficiently made. Concluding, the court said:

> The appellant is chargeable with notice of the fact that the tubes were not merely intended as conduits for heat, but that they were intended to support and sustain the boiler heads, and it failed to install them in such manner that they would afford proper support in that regard. The appellant was chargeable with knowledge of the dangers to those lawfully on the premises in the event that the boiler head gave way, owing to its negligence in making the repairs. A steam boiler is inherently dangerous, and one who repairs it owes a duty of proper care to avoid injury, not only to the property and employees of the purchaser, but to all persons who may be thereby subjected to injury, and to that end must perform his work properly.

Perhaps You Can Render Valuable Service to Your Country

Important chemical and other technical engineering work necessary for the prosecution of this war is being carried on by the Bureau of Mines Experiment Station, at Washington, D. C. The services of trained men of the following classifications are urgently needed: Bacteriologists, biologists, chemists (inorganic, organic, physical and electro-), chemical engineers, draftsmen, electrical engineers, instrument makers, laboratory assistants, laborers, machinists, physiologists, plumbers, steamfitters, stenographers, skilled labor of various kinds.

If your training fits you for any of these occupations, send to the Bureau of Mines, American University Experiment Station, Washington, D. C., for blank forms. When properly executed and returned, these forms will be placed on file, and when a vacancy occurs you will be considered for it and will be notified if your services are desired.

If you are a registrant in the draft and have not yet been ordered to camp, it may be possible to have you immediately inducted into the service for work here.

If you are not in the draft, but feel that you wish to serve your country in the present crisis, you can enlist or serve as a civilian. Serve your country where you can serve it best.

A Washington contemporary says it leaked out in the Department of the Interior that the commission of eminent scientists appointed by Secretary Lane to judge whether the inventor, Garabed Giragossian, is right or wrong, the names of whom have been kept a secret, will be headed by James Ambrose Moyer, of Norristown, Penn. Professor Moyer is Director of the State Department of University Extension in Massachusetts and has been in charge of the Department of Mechanical Engineering at the Pennsylvania State College; also an engineer with Westinghouse Church Kerr & Co. and engineer of the Steam Turbine Department of the General Electric Co. He is the author of works upon Steam Turbines, Thermodynamics and Power-Plant Testing.

Tube Thickness Considered at Massachusetts Hearing

A recommendation that the minimum thickness of tubes in water-tube boilers be standardized in accordance with the A. S. M. E. Code and inserted as an additional section in the Massachusetts Code of Boiler Rules was presented at Boston, May 2, to the Board of Boiler Rules by the Mutual Boiler Insurance Co., Boston. This matter and a petition that the rules be altered to permit the use of the Breakey type of automatic gage-glass cutoff were the only subjects brought before the board at the semiannual hearing, at which George A. Luck, deputy chief of the Boiler Inspection Department of the Massachusetts District Police, presided.

The first petition urged the addition of Sec. 7 to Part 3 of the 1917 Rules, to read as follows:

Tubes for Water-Tube Boilers

The minimum thicknesses of tubes, circulating pipes and nipples used in water-tube boilers, measured by Birmingham wire gage for maximum allowable working pressures not exceeding 165 lb. per sq.in. shall be as follows:

Diameters under 3 in	No. 12 B.w.g.
Diameters of 3 in. or over, but under 4 in	No. 11 B.w.g.
Diameters of 4 in. or over, but under 5 in	No. 10 B.w.g.
Diameter of 5 in	No. 9 B.w.g.

The above thicknesses shall be increased for maximum allowable working pressures above 165 lb. as follows:

Above 165 lb., but not over 235 lb	1 gage
Above 235 lb., but not over 285 lb	2 gages
Above 285 lb., but not over 400 lb	3 gages

Tubes over 4 in. in diameter shall not be used for maximum allowable working pressures above 285 pounds per square inch.

John A. Collins, secretary of the Mutual company, urged the above incorporation on the ground of increased safety. He said that water-tube boilers are now being built in Massachusetts for 200 lb. pressure, using No. 10 B.w.g. tubes. For the past fifteen years the Mutual company has been recommending even heavier tubes than are called for in its petition. Nothing was included in the section relative to tube quality, but in answer to an inquiry, Mr. Collins stated that seamless-drawn tubes are greatly to be preferred to lap-welded. This was not incorporated in the recommendation because of the great difficulty today in obtaining seamless-drawn tubes.

J. F. Molloy, chief inspector of the Mutual company, said that he knew of a public-utility company in Massachusetts which is installing ordinary standard-gage No. 10 tubes in water-tube boilers for 200 lb. pressure; and it is not known what the actual thickness of the tubes is. These tubes may run as small as No. 11 or No. 12 for all that the inspecting company can tell. Another plant, soon to be operating at 300 lb. pressure, is putting in No. 7 gage. Under the present Massachusetts rules the use of No. 25 gage would be possible in this case. Mr. Molloy said that most accidents his company had noted in water-tube boilers came from the rupture of the tubes. No trouble has been experienced from the collapsing of fire tubes. The company has issued specifications for No. 11 gage tubes in boilers operating at 175 lb., in some of its practice. It is an open boast today among boilermakers that they would rather bid on the Massachusetts Code than on the A. S. M. E. There was no opposition to the proposed new section.

L. I. Breakey, Marshall, Mich., petitioned the board for a change in Rule No. 27, Part 3, Sec. 6, page 98, Rules of 1917, which prohibits the use of an automatic shutoff valve on a water-glass connection. The petition stated that a large number of states have changed this rule so as to admit the use of automatic shutoffs, of which there are now several makes. The Breakey shutoff is indorsed by the Ohio State Board of Boiler Rules and the Pennsylvania Industrial Board as applied to steam boilers, and it meets the A. S. M. E. Code as governing water gages. The proposed change in the rule reads as follows:

No water-glass connection shall be fitted with an automatic shutoff valve except where the automatic shutoff valves are so constructed that the two connections to the water glass can be blown through and the steam connection cannot be entirely closed thereby; means must also be provided for the renewal and inspection of the upper and lower ball check valves while the boiler is under working pressure.

There was practically no discussion of this recommendation with the exception of a comment by James Stewart, Stewart Boiler Works, Worcester, Mass., who queried the continuous reliability of any spring-actuated device and who emphasized the great importance of making such equipment foolproof. The hearing was then closed.

Government Will Open Up Fuel Oil Reserve

The naval fuel-oil reserve in California will be opened up by the Government immediately to prevent an oil famine. Assurance to this effect was given to a delegation of prominent newspaper publishers from the Pacific Coast after conferences with Secretary of the Navy Daniels, Bernard M. Baruch, chairman of the War Industries Board; Mark L. Requa, director of the oil division of the United States Fuel Administration, and representatives of eighty litigants who have numerous claims against the property now included in naval reserve No. 2.

Requa, the oil director, after the conference served notice upon the litigants that if they do not adjust their differences with the Government within two weeks so amicable settlement of disputes can be made after the war, the fields will be commandeered as a war measure.

Secretary Daniels, who took the precaution four years ago to conserve the great oil fields, gave his hearty consent to the opening up of the naval fuel-oil reserves.

Baruch said he not only could see the great and pressing need for it, but would suggest to President Wilson the commandeering of the entire Pacific Coast oil industry, if such steps were necessary.

The publishers, who were headed by F. W. Kellogg, of the San Francisco *Call*, first went to see Baruch. They explained the serious fuel-oil situation that faced not only the coast but the whole country.

They said fuel commissioners had told them there were in storage on Jan. 1, 19,000,000 bbl. of fuel oil. There will be produced under the present maximum conditions 78,000,000 bbl. of oil this year. The consumption at the present rate will require 96,000,000 bbl. This would leave only 1,000,000 bbl. at the end of the year. The reserves are decreasing at the rate of 1,500,000 bbl. a month.

Of the 2,400,000 hp. produced on the coast, nearly 75 per cent., or 1,500,000, is developed by fuel oil, 380,000 by water, 100,000 by coal and 100,000 by gas.

Fifty-seven per cent. of all the fuel oil is now used by railroads and vessels, including naval ships. The shipping board's program contemplates the use of fuel oil in about 35 per cent. of the merchant fleet. Unless this is met by additional and immediate increase in production industries depending on fuel oil will be paralyzed.

According to *Commerce Reports*, a new syndicate has been formed by Einar Steensrud, of Skien, Norway, for the consolidation and developing of a number of small waterfalls, aggregating 200,000 hp. The present intention is to utilize this power for the manufacture of nitrate, aluminum or carbide, according as the demand develops. The annual report of the Norsk Hydro has appeared, covering the year ended June 30, 1917. The net profit was $6,650,000, compared with $4,900,000 in the previous year. The capital stock is $15,450,000. This company operates waterfalls of about 300,000 hp. for the production of electrochemical commodities like nitrates and carbide. In the production of all of these commodities great heat is generated, and heretofore much of it has been wasted. By a new arrangement the waste heat is now to be utilized for the production of low-pressure steam to operate turbines.

The noncompressibility of water, coupled with the thickness of some men's heads, has helped the repair shops to several millions of dollars of work. We cannot change the nature of water, but we can do something with the men's heads.—*Marine Engineering.*

Detroit Engineering Societies' Joint Meeting

The Detroit Engineering Society and the Detroit Section of the American Society of Mechanical Engineers held a joint meeting Friday evening, May 3, in the Board of Commerce Auditorium. Dean Cooley, of Michigan University, announced a course in elementary drawing and training for women at the summer school this year, to meet the demands of the drafting room. These women will be taught to do the more elementary work, thus relieving the regular draftsmen and designers. The movement was promised the hearty coöperation of both societies, which passed a resolution to place the graduates and give the matter the necessary publicity to interest other schools in this line of endeavor.

The paper of the evening was by R. H. Kuss, consulting engineer, of Chicago, on "Coal Conservation as Applied to Boiler-Room Operation." Mr. Kuss pointed out that coal is the greatest factor in this war, one-third of the cost of living reverting to this product. A table of the use of coal was shown.

ESTIMATED EFFICIENCY WHEN BURNING BITUMINOUS COAL

	Stationary Plants			
	High	Low	Locomotive	Domestic
Poor practice, per cent	50	40	60	30
Fair, per cent	64	56	66	40
Good, per cent,	72-74	62	70	50
Available, per cent	76	68	72	55
Available decrease, per cent	12	14	9	15
Available saving, tons	25,800,000		17,100,000	20,250,000

Total available saving, 63,150,000 tons on 1917 basis.

These figures are based on observations and statistics for 1917. The available percentage is not a theoretical saving, but is based on actual practice in carefully watched plants. The available decrease is the percentage that could have been saved by careful methods, with improvements in present equipment. Considering that the output of bituminous coal for 1917 was 540,000,000 tons and the estimated requirement for 1918 is 619,000,000 tons, the necessity of preventing this waste may readily be seen.

Mr. Kuss put the problem to the engineers as their own. He showed that under new district regulations coal would be burned in fireboxes not fitted for its proper combustion and that it is the engineers' duty to see that janitors and owners of homes are taught to fire properly.

He pointed out the steps to be followed in good practice, such as tight fireboxes; the necessary combustion-chamber construction so that the air and distilled gases may have time to mix and combine before coming in contact with the relatively cold surfaces; frequent cleaning of both sides of heating surfaces. Great stress was laid on the draft control and the proper supply of air, it being as wasteful to use too much air as to use too little. Mr. Kuss spoke of the difficulties the efficiency engineers would encounter and suggested ways of overcoming them, such as: Keep in touch with the chief operator, he knows the conditions better than anyone else; study the plant over a long period; talk to the men so that the suggestions for improvement may come from them, and in some cases use opposition so that the operator will work hard to prove his point.

The engineers were warned that in the near future the Government would compile a classification list of the boiler plants in an attempt to show the grade of equipment, and that coal will be distributed on virtue of existing boiler plants.

The societies passed a resolution to maintain a joint committee to aid the Fuel Administration along the lines of good practice.

Responsibility for Injury in Horse-Play

If a fireman employed in a boiler room left his employer's premises to chase a man who had called him "Turkey," and was injured while so engaged, there can be no award under the New York Compensation Act on a theory that the accident occurred in the course of the fireman's employment. (New York State Industrial Commission's December, 1917, Bulletin, p. 82. Sullivan vs. Beach Gasper Company.)

Thermal Values of Soft Coals

From Selected Free-Burning and Caking Soft Fuels. From U. S. Geological Survey Bulletin No. 332 and U. S. Bureau of Mines Bulletin No. 23.

State	Test No.	Kind of Fuel	County	B.t.u per Lb
Alabama	375	Soft—caking	Bibb	13,671
Alabama	484	Soft—free-burning	Jefferson	14,447

Compensation Act Applied

A novel question was presented to the Connecticut Supreme Court of Errors in the late case of Richards vs. Indianapolis Abattoir Co., 102 Atlantic Reporter, 604. Plaintiff, an employee engaged in work disconnected from the company's power plant, found it necessary to wait for about fifteen minutes before he could use an elevator in proceeding with his work, and sat down on a near-by keg in the power plant, close to a firebox and boiler. Being tired, he dozed off to sleep and awakened a few minutes later to find that his clothing had caught fire, either from radiated heat of the firebox or from a flying spark. His demand for compensation to cover resulting injury was resisted on the ground that he was not injured in the course of his employment, but the court permitted recovery, saying: "The falling asleep of the claimant was natural in the case of a man who has been engaged in hard work for the whole morning in the cold, and who at the time was sitting in a hot place. The falling asleep was not the result of any conscious effort on the part of the claimant, but came simply from drowsiness which crept over him as the result of his previous exertion. The accident occurred when the claimant was at a place where he might reasonably be. There was no turning aside on his part, no attempt to serve ends of his own."

New Publications

ELEMENTARY MECHANICS FOR ENGINEERS. By Clifford Newton Mills. Published by D. Van Nostrand Company, New York City. Cloth, 5 x 7¼ in.; 127 pages. Price $1.

This is another of a number of similar books which have appeared in the last three or four years and is arranged for students who have previously studied trigonometry. It is intended as a basis for a semester's work of three hours per week. The subject matter is divided into three parts—kinematics, kinetics and statics. Throughout many problems have been given, so that the students may master the subject by working on the many problems given The problems are well presented and for the man who has been through trigonometry, the book is well worth a dollar.

HANDBOOK OF ENGINEERING MATHEMATICS. By Walter E. Wynne and William Spraragen. Published by D. Van Nostrand Co., New York City. Flexible leather, 4¾x7 in.; 220 pages. Price, $2.

Many engineers and students will greatly appreciate this little book, which, as the introduction by Prof. Ernest J. Berg, consulting engineer. General Electric Co., Schenectady, N. Y., states is intended primarily for students in engineering schools and colleges and should serve as a convenient reminder of things that are easily forgotten, but are likely to be needed in their later work. This is certainly the most useful purpose of the book.

The authors have endeavored to supply a ready means of reference to theoretical and applied mathematics as used in engineering, and it includes the underlying engineering data and applications as well as the mathematical formulas. The first 89 pages are devoted to pure mathematics including everything from algebra to calculus and theoretical mechanics, the latter embracing gravity, inertia, impact forces, friction, etc. The remaining chapters treat of the mechanics of materials, hydraulics, flow of liquids, electricity, to measurement and physical and chemical constants. Pages 185-213 are devoted to tables of circumferences and areas of circles; powers, reciprocals; common logarithms; natural logarithms; trigonometric functions; hyperbolic sines and cosines.

It is a mighty good little book to have around to refresh the memory, and we shall be glad to keep it on the shelf near our desk.

STEAM TURBINES. By William J. Goudie. Published by Longmans, Green & Co., New York City. Size 6 x 9 in.; 519 pages; illustrated Price $4.

This is one of two unusually good books on steam turbines to appear in recent months. [The other is "Steam Turbines," by G. J Meyers, Lieut. Comm. U. S. Navy, and published by the United States Naval Institute; it will be reviewed in an early issue of "Power".] It has been the aim of Mr. Goudie to present a volume to suit the requirements of engineering students, chiefly, though there is indeed much to interest the designer and operator; in fact, the book is one that should be of considerable help to anyone interested in steam turbines. Condensers and condensing apparatus are not discussed.

The chapter on classification of turbines has some diagrams showing the behavior of velocity and pressure in turbines of the various types, which we are glad to see in a book of this kind. Such diagrams are of considerable aid to the student particularly. Throughout the book there are many excellent line drawings of sections of turbines of various types; in these drawings details are well illustrated.

The book is particularly pleasing because one finds something of what one looks for —and one looks for many data, drawings, tables, etc., on turbines these days This thoroughness, which is true of all the sixteen chapters, makes the volume the kind one wants within reach. We have had our review volume a long time, using it for reference and checking—the best way to review a book, of course. The chapter headings are: Classification of Turbines; Impulse Turbines; Reaction Turbines; Combination Turbines; Properties of Steam; Entropy Diagrams; Nozzles; Blading; Rotors; Mechanical Losses; Reheat Factors; Steam Consumption; Determination of General Proportions of Turbines. There are three chapters dealing with this last subject, and in them the author has given many excellent formulas. The last chapter deals with governing.

ELEMENTS OF FUEL OIL AND STEAM ENGINEERING. By Robert Sibley and Charles H. Delany. First Edition Published by the Technical Publishing Co., San Francisco, Calif. Cloth, 6 x 9 in.; 320 pages; illustrated. Price, $3.

The authors have had considerable experience in fuel-oil burning, on the Pacific Coast particularly. In their preface they state that it has been their underlying aim to study fuel-oil power-plant operation and the use of evaporative tests in increasing the efficiency of oil-fired plants. To accomplish this end, the subject matter has been treated in three main divisions: First. an exposition of the elementary laws of steam engineering; second, the processes involved in the utilization of fuel oil in the modern power plant; third, the testing of boilers when oil-fired. In treating the first subdivision, the elementary laws of steam engineering are set forth in a new manner in that the viewpoint is taken from that of the oil-fired instead of the coal-fired plant operator. In the second division the results of considerable labor and analyses are set forth from the collecting and collating of data involved in boiler-furnace and fuel-oil tests, many of which have appeared heretofore in disconnected form and in widely varying sources. In the first subdivision the authors have given definite suggestions for fuel-oil tests—largely suggestions recently presented personally by them at the invitation of the power test committee of A. S. M. E. The matter which deals altogether with fuel oil does not begin until Chapter 12 is reached; but from here on the authors have placed much that is of value on the subject, which for the East particularly, grows in importance. One can justly criticize some of the illustrations used in the book because of their smudgy appearance, which is not due to printing. The text matter is so well arranged that it seems unfortunate that so many of the illustrations should have been reproduced from cuts that were evidently made direct from other printed matter. There are, however, some excellent halftones throughout the book, among which are the views of the economy measuring apparatus installed at the Long Beach plant of the Southern California Edison Co.

Altogether the book is a desirable addition to the few volumes now available on this subject.

ELECTRIC WELDING MANUAL

The Wilson Welder and Metals Co., New York City, has issued a 45-page booklet devoted in part to instructions for installing and using its system of electric welding. Wiring diagrams and tables, dimensions of motor generators, brackets, etc., are given Tables showing the melting points of various metals and alloys, and instructions for the care of metals appear in the booklet. Pages 37-39 show typical examples of prepared and finished work.

PURCHASING COAL BY SPECIFICATION AND METHODS OF SAMPLING

The Pennsylvania State College, Engineering Experiment Station, has completed a reprint from the annual report of 1913-14 in which are set forth methods of purchasing coal by specification and of sampling coals for analyses. The subject is treated of by J. A. Moyer and J. B. Calderwood. The pamphlet contains 158 pages and gives the methods of gathering coal samples as used by the Bureau of Mines, Interboro Rapid Transit Co., New York City, United States Steel Corporation, General Electric Co., and Detroit United Railways. Methods of coal sampling and analyses of the American Chemical Society and of the American Society of Mechanical Engineers, also are given. Discussion of the determination of volatile matter in coal is given on page 149 of the bulletin and is of interest. We understood that the bulletin is for distribution free.

U. S. STEEL CORPORATION'S METHODS FOR SAMPLING AND ANALYZING GASES

The second edition of this valuable pamphlet (6 x 9 in., 60 pages) by the Chemists' Committee of the corporation, has been completed. In the methods set forth in the bulletin there has been an unwavering purpose to eliminate, as far as possible, tedious analytical procedure and the use of cumbersome forms of apparatus. It has been desired to adopt methods correct in principle which, in conjunction with the simplified apparatus, will insure the requisite expediency at times so necessary in commercial work without an appreciable sacrifice in accuracy of results The pamphlet deals, of course, with all the gases met with by the various companies in the corporation. Among these are blast-furnace gas, the analysis of which becomes of increasing importance because of the extensive use of this gas in waste heat boilers; producer gas; byproduct gas; flue gas; and natural gas.

On page 48 an interesting table is given: The products of combustion from burning pure carbon would contain 20.9 per cent. carbon dioxide, since it has the same volume as the oxygen used The byproducts of combustion of coal contain less CO_2 than 20.9 due to the fact that the hydrogen of the coal requires oxygen from the air, resulting in more nitrogen than if pure carbon were burned The percentages of carbon dioxide in the products of combustion resulting from perfect combustion of various coals have been calculated and are given here for comparison.

	Per Cent.
Anthracite culm, Scranton, Penn.	19.5
Semi-anthracite, Coalhill, Ark.	19.0
Semi-bituminous, W. Va.	18.8
Bituminous coking, Connellsville, Penn.	18.8
Bituminous noncoking, Hocking Valley, Ohio	18.7
Sub-bituminous, Unita County, Wyo.	18.9
Lignite, Milan County, Tex.	19.2

The latter pages of the booklet have three valuable tables giving the chemical symbol, specific gravity, weight, heat of combustion, volume of oxygen necessary for combustion, and the products of combustion. The second table, on aqueous vapor, gives the pressure in inches of mercury for different degrees F., and the weight in grains per cubic foot The third table gives factors for reduction of the volume of gas at standard conditions of 62 deg. 30 in. mercury.

The booklet is the best to come to our attention on the subject of gas sampling and analyzing.

J. N. Camp is chairman of the Chemists' Committee, United States Steel Corporation, Carnegie Building, Pittsburgh, Penn.

Obituary

E. C. Meier, president of the Heine Safety Boiler Co., died of heart failure at the Manufacturers' Club, Philadelphia, Tuesday afternoon, May 7, aged 50. Mr. Meier was attending a meeting of officials of the Emergency Fleet Corporation for which his company is making many boilers.

Personals

E. E. Maher has been appointed Chicago district manager of the Terry Steam Turbine Co., with offices at 1328-29 McCormick Building.

Norman G. Reinicker, formerly with the New York Edison Co., is now with the Du Pont interests in charge of the power plant at Nashville, Tenn.

John D. Stout has been appointed New York district manager of the Terry Steam Turbine Co. Mr. Stout has been assisting Mr. Herbert, formerly in complete charge of the district, but who will now have to devote his entire time to navy and marine requirements.

W. W. Erwin, for the past 18 years connected with the New York Edison Co., successively as mechanical draftsman, chief draftsman and superintendent of construction, has been appointed chief operating engineer of the company to succeed the late J. P. Sparrow.

The Association of Iron and Steel Electrical Engineers announces the following meetings: The Cleveland District Section on May 25 at Hotel Statler. A. E. Hogrebe will discuss the subject of Cranes. The Philadelphia Section will meet on June 15 and will hold its annual outing on this date at Valley Forge to take the place of the regular monthly technical session.

Engineering Affairs

The American Society for Testing Materials will hold its twenty-first annual meeting at Atlantic City, N. J., June 25-28, with headquarters at the Hotel Traymore.

The National Association of Master Steam and Hot-Water Fitters will hold its twenty-ninth annual convention in Chicago, June 3-5, with headquarters at the Hotel Sherman.

The American Society of Heating and Ventilating Engineers will hold its summer meeting at Buffalo, N. Y., June 26-28. This meeting is being held earlier than usual, partly to accommodate the members of the National District Heating Association, which association will not hold a meeting this year.

The American Society of Mechanical Engineers will hold its spring meeting at Worcester, Mass., June 4-7. The meeting will open and registration take place at the Hotel Bancroft on Tuesday forenoon. Wednesday will be New England Day. In the forenoon George H. Haynes will read a paper on "The Small Industry in a Democracy," and J. E. Rousmaniere one on "The Textile Industry in Relation to the War." These will be followed by visits to Crompton & Knowles Loom Works and to the plant of the Royal Worcester Corset Co. In the afternoon papers will be presented upon subjects relating to New England's industries under war conditions, and the following at the general session: "Foundry Cost and Accounting System," by W. W. Bird; "The Public Interest as the Bed Rock of Professional Practice," by Morris L. Cooke; "Moisture Re-absorption of Air-Dried Douglas Fir and Hard Pine, etc.," by Irving H. Cowdrey; "A High-Speed Air and Gas Washer," by Lieut. J. L. Alden; "Investigation of the Uses of Steam in the Canning Industry," by J. C. Smallwood. On Thursday forenoon at the general session will be given the following papers: "Efficiency of Gear Drives," by C. M. Allen and F. W. Roys; "Self-Adjusting Spring-Thrust Bearing," by H. G. Reist; "Air Propulsion," by Morgan Brooks; "The Elastic Indentation of Steel Balls Under Pressure," by C. A. Briggs, W. C. Chapin and H. G. Heil; "Electric Heating of Molds," by Harold E. White; "Stresses in Machines When Starting or Stopping," by F. Hymans. At the Fuel Session the paper will be: "An Investigation of the Fuel Problem in the Middle West," by A. A. Potter, and topical discussion on fuel economy, to be arranged for by the Fuel Conservation Committee of the Engineering Council. The various sessions will be held at the Worcester Polytechnic Institute.

Miscellaneous News

A Boiler Exploded at the Houston and Texas Central Railway shops at Ennis, Tex., on Apr. 13, killing one young man and seriously injuring another man.

Watervliet Arsenal is in urgent need of machinists for the conduct of its establishment and calls for the assistance of all instrumentalities which are available. One thousand skilled mechanics must be procured before Sept. 1. The character of the work and the high rates of pay should prove attractive to machinists.

Although 6600 Volts of electricity apparently passed through the body of John Hanifan, a lineman for the Virginia Western Power Co. at Ronceverte, he survived. When Hanifan's foot slipped his body came in contact with the high-power wire and a monkey wrench he carried came in contact with a guy wire, establishing a circuit. The "circuit-breaker" in a substation worked promptly, shutting off the current.

The Potomac Light and Power Co., of Martinsburg, W. Va., according to the statement of a man connected with the company, is expending $250,000 for machinery and transmission lines for a plant at Dam No. 5 on the Potomac River, about 10 miles northwest of Martinsburg. By the improvements to be made the company expects to increase its capacity 2500 hp. In addition to the steam-power plant at Martinsburg, a plant will be built at dam No. 4 and negotiations have been completed with the Hagerstown & Frederick Railway Co. under the terms of which the latter company will use the surplus power of the Potomac company when needed, and vice versa.

Business Items

The Clarage Fan Co., of Kalamazoo, Mich., announces the removal of its Chicago office to the Conway Building, 111 West Washington St., Room 1666, with Gardner J. Thomas in charge.

The Sprague Electric Works, announces the removal of its St. Louis office from the Chemical Building to the Pierce Building, Room 1352; and the removal of its Boston office from 201 Devonshire St., to 84 State St., Room 906.

The Alberger Pump and Condenser Co. announces the election of its officers as follows: Chairman of the Board of directors, George Q. Palmer; president, William S. Doran; vice-president, William R. Wilson; secretary, Richard C. Williams; treasurer, Frederick A. Brockmeir.

The Vulcan Soot Cleaner Sales Co.'s removal of main offices from Chicago to Du Bois, Penn., does not affect the Vulcan Fuel Economy Co., which controls boiler-room and fuel-conservation appliances, and remains at 230 South La Salle St., Chicago, with representatives in the chief manufacturing centers.

The Havard Coal Meter, which has been in general use for a number of years for measuring coal in boiler rooms as fed to boilers, has been awarded the Certificate of Merit by the Franklin Institute of the State of Pennsylvania. The award reads as follows: "In consideration of the invention of a meter for the measurement of granular material, which combines simplicity of construction with reliability in operation, is automatic in action and accurate in measurement within a reasonably small limit, the Institute awards the Certificate of Merit to Oliver D. Havard, of Allentown, Penn., for his invention of The Havard Coal Meter.

Trade Catalogs

A Business Trip With a Railway President. Perolin Railway Service Co., St. Louis, Mo. Pp. 16; 9 x 12 in. The story of Perolin as a boiler-metal treatment attractively presented as a drama in three acts, under the above title.

Lower Pumping Costs with E-M Synchronous Motors. Electric Machinery Co., Minneapolis, Minn. Bulletin 183. Pp. 23; 8½ x 11 in.; illustrated. Outlines in a general way the subject of centrifugal-pump development; the selection of a motor to drive a pump, etc.

The Smooth-On Manufacturing Co., of Jersey City, N. J., will send to anybody who requests it, a copy of the 16th edition of its new instruction book, which contains 144 pages of interesting and illustrated reading matter, showing how the different Smooth-On iron cements are used for repairing purposes.

NEW CONSTRUCTION

Proposed Work

N. H., Manchester—The Manchester Traction, Light and Power Co. has had plans prepared for the erection of a boiler house near Mast St. L. J. Farrell, Engr.

N. Y., Albany—The Chasm Power Co. of Chateaugay, plans to issue $25,000; the proceeds will be used to build an auxiliary power house and install and equip same with necessary machinery. W. T. Thayer, Gen. Mgr.

N. Y., New York—The United Electric Light and Power Co., 515 West 141st St., has purchased a site on West 97th St. and plans to build a power station on same.

N. Y., Utica—The Augusta Knitting Mills, 307 Niagara St., will soon award the contract for the erection of a 2 story factory. Estimated cost, $30,000. Motors, blowers, etc., will be installed in same.

N. J., Newark—The Heller and Merz Co., Hamburg Place, will soon receive bids for the erection of a power house. R. G. Corey, 39 Cortland St., New York City, Arch.

Md., Cumberland—The Kelly Springfield Tire Co., Cook St., Akron, is building a new plant here. Work includes the construction of a power station. Estimated cost, $1,000,000.

W. Va., Charleston—The Virginia Power Co. plans to build a 16 mile transmission line from here to Nitro. H. G. Scott, Gen. Mgr.

W. Va., Harpers Ferry—The Northern Virginia Power Co. plans to issue $500,000 bonds; the proceeds will be used to build a hydro electric plant. D. M. Swink, Winchester, Va., Gen. Mgr.

Ga., Reidsville—City voted to issue $10,000 bonds for the installation of an electric lighting plant.

Fla., Sarasota—City plans to install an electric lighting and power plant.

Ala., Goodwater—The Central of Georgia Ry. plans to build a coal chute and install electric power equipment. C. K. Lawrence, Ch. Engr.

Miss., Purvis—City will soon receive bids for the erection of an electric lighting plant. X. A. Kramer, Magnolia, Engr. Noted May 7.

La., Gueydan—City plans to install an electric lighting plant. About $15,000 is available for the project.

Ohio, Cincinnati—The Andrews Steel Co. 9th and Lowell Sts., Newport, plans to build a 6000 kw. electrical unit at its plant. W. N. Andrews, Secy.

Ohio, Cleveland—The Army and Navy Post, Grand Army of the Republic, care J. J. Sullivan, Central National Bank, Rockefeller Bldg., plans to build a memorial building and install low pressure boiler for steam heat.

Ohio, Cleveland—The J. P. Stotter Co., Leader News Bldg., plans to build a hotel on Euclid Ave and East 71st St., and install elevators, heating boilers, etc. Total cost, $200,000.

Ohio, Columbus—City is having plans prepared for the installation of a new heating system in the city hall. About $19,000 has been appropriated for this project.

Ohio, Gambrinus—(Canton P. O.)—The Wheeling and Lake Erie R. R., Electric Bldg., Cleveland, plans to build power and round houses here. About $95,000. W. R. Rohbock, Electric Bldg., Cleveland, Engr.

Ind., Indianapolis—The Citizens Gas Co. 47 South Penn St., plans to improve and extend its plant. Estimated cost, $750,000.

Wis., Peshtigo—T. A. Pamerin has purchased the local electric lighting plant and plans to install additional equipment and build a dam.

Wis., Stevens Point—The Jackson Milling Co., Grand Rapids, plans to build a 2 story, hydro electric plant About $500,000. L. A. Geers, Grand Rapids, Engr

Iowa, Monticello—The Monticello Electric Co. plans to extend its electric transmission lines from here into Linn County G. Adamson, Ch. Engr.

Kan., Alden—N. L. Jones has been granted a franchise by the City for the construction, maintenance and operation of an electric light and power distributing system.

Kan., Garnett—City plans an election to vote on $65,000 bonds; the proceeds will be used to improve its electric lighting plant and water works system. Black & Veatch, Inter State Bldg., Kansas City, Mo., Engrs.

Kan., Topeka—The St. Frances Hospital will soon award the contract for the erection of a brick and reinforced power house and laundry. Estimated cost, $20,000. E Forsblom, Topeka, Arch.

Neb., Norfolk—The Board of Directors of the State Insane Hospital, will soon award the contract for the erection of a power house and ward building. Estimated cost, $70,000. J. C. Stitt, Arch.

Mo., Kansas City—The Kansas City Railways, 303 Montgall St., will soon award the contract for the erection of a substation on Oak St. Estimated cost, $25,000. C. E. Fritts, 15th and Grand Ave., Engr. Noted Oct. 7

Mo., Lees Summit—The Green Light and Power Co. plans to extend its transmission lines from here to Little Blue.

Mo., West Plains—The Missouri Iron and Steel Corporation plans to build a large power plant near Henderson. Estimated cost, $750,000.

Tex., Denison—City plans to build an electric lighting plant.

Tex., Nixon—The Nixon Electric Light and Power Co., plans to install an alternator. W. L. Hoover, Mgr.

Okla., Bixby—City plans to install an electric lighting plant.

Okla., Jennings—City plans an election soon to vote on $25,000 bonds for an electric lighting plant.

Ariz., Snowflake—The Snowflake and Taylor Irrigation Co. plans to build a hydro electric plant. Plans for the project will mature about July 8.

Wash., Seattle—The Board of Public Works plans to build a sanatorium and will install a steam heating plant in same. About $60,000. A. H. Dimock, City Engr.

Ore., Estacada—The Portland Ry. Light and Power Co., Portland, has been granted permission by the Government to build a large power plant and dam here. About $1,000,000. O. B. Coldwell, Bway and Alder Sts., Portland, Gen. Supt.

Ore., Salem—The Crown Willamette Paper Co., Pittock Blk., Portland, has applied for permission to develop 200 second feet of water from Youngs River, near Astoria. Plans include the construction of a power house, dam, etc. Estimated cost, $150,000.

Ore., Toledo—The Lincoln County Light and Power Co. plans to enlarge its capacity by installing a 2000 hp. turbine and dynamo. J. Paquet, 112 East 12th St., Portland, Pres.

Calif., Modesto—The Sierra and San Francisco Power Co plans to build a hydro electric plant on the Middle Fork of the Stanislaus River. M. C. McKay, 58 Sutter St., San Francisco, Supt.

N. S., Barrington—The Town plans to build an electric lighting and power plant Estimated cost, $8000.

N. S., Berwick—Town plans to build an electric lighting and power plant. H. A. Cornwell, Clerk.

N. B., St. John—T. McAvity and Sons, Ltd., plans to install a new 550 hp. steam power plant in its plant now being built.

Ont., Hamilton—The Board of Governors of the City Hospital has plans under consideration for the construction of a power plant here.

Ont., Toronto—Milton & Prentice Traders' Bank Bldg., is in the market for two 250 hp. vertical steam engines.

CONTRACTS AWARDED

Mass., Middleton—Essex County Commissioners, Salem, have awarded the contract for the installation of a central heating plant, to Lynch & Woodward, 287 Atlantic Ave., Boston. Estimated cost, $35,764.

R. I., East Greenwich—The Andrews Mill Co., 221-4th Ave., New York City, has awarded the contract for the erection of a 2 story, 45 x 80 ft. brick and steel power house and a brick and steel weave shed, to be erected here, to the C. I. Bigney Constr. Co., 89 Weybosset St., Providence. Estimated cost, $200,000.

Conn., Bridgeport—The United Illuminating Co. has awarded the contract for alterations and improvements to its local power house, to the New England Iron Works, 94 Commerce St., New Haven.

N. Y., Buffalo—The Delaware, Lackawanna and Western R.R. has awarded the contract for the erection of a power house at East Buffalo, to J. W. Cowper, Fidelity Bldg.

N. Y., Mohawk—The Elastic Spring Knit Corporation, East Main St., has awarded the contract for the erection of a knitting mill to F. R. Edick, West Main St. Estimated cost $30,000. A steam heating plant will be installed in same.

Penn., Erie—The Board of Education has awarded the contract for the erection of a new school, to Sutherland Building and Contracting Co., Syndicate Trust Bldg., St. Louis. Boilers and a vacuum heating system will be installed.

Del., Wilmington—The Mullins Store Co. has awarded the contract for the installation of a heating plant, to Gawthrop & Bro. Co. Estimated cost, $11,270.

Va., Richmond—The Virginia Ry., and Power Co. has awarded the contract for improvements and alterations to its sub station, to Nicholas & Lindermann, 522 Sea Board Blk., Norfolk. Estimated cost, $11,700.

Ohio, Hamilton—The Shuler and Benninghofen Mills Co., Lindenwald St., has awarded the contract for the erection of an addition to its boiler house, to G. Lingler. Estimated cost, $7500.

Neb., Sidney—The Town has awarded the contract for improvements to its electric lighting and water works plant, to the O'Fallan Supply Co., Denver, Colo. Estimated cost, $30,592.

Ariz., Snowflake—The Snowflake and Taylor Irrigation Co. has awarded the contract for the installation of an electric lighting and power plant, to H. T. Loyd, Wickenberg. Noted Oct. 16.

Wash., Cheney—F M. Martin Grain and Milling Co., Hutton Bldg., Spokane, has awarded the contract for the erection of a concrete mill to Huetter Construction Co., Spokane. Equipment including motors, electric lighting outfit, etc., will be installed.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular Current	Individual Current
Buckwheat	$4.60	$7.10—7.35
Rice	4.10	6.65—6.90
Boiler	3.90	....
Barley	3.60	6.15—6.40

BITUMINOUS

Bituminous not on market

Pocohontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.00 a year ago.

*All-rail to Boston is $2.60. †Water coal

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* are as follows:

ANTHRACITE

	Circular Current	Individual Current
Pea	$4.90	$5.65
Buckwheat	4.45@5.15	4.80@5.50
Barley	3.40@3.65	3.80@4.50
Rice	3.90@4.10	3.00@4.00
Boiler	3.65@3.90	....

Quotations at the upper ports are about 5c higher.

BITUMINOUS

	F.o.b. N. Y. Gross	Mine Price Net	Gross
Central Pennsylvania..	$5.06	$3.05	$3.41
Maryland—			
Mine-run	4.84	2.85	3.19
Prepared	5.06	5.05	3.41
Screenings	4.50	2.55	2.85

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty, Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The ratte to the upper ports is 5c. higher than to the lower ports

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Current	One Yr. Ago	Current	One Yr Ago
Pea	$3.45	$2.80	$4.35	$3.70
Barley	2.15	1.50	2.40	1.75
Buckwheat ..	3.15	2.50	3.75	3.40
Rice	2.65	2.00	3.65	3.00
Boiler	2.45	1.80	3.55	2.90

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes...	$2.65—2.80	$3.35—3.50
Mine-run	2.40—2.55	3.10—3.25
Screenings	2.15—2.30	2.85—3.00

Smokeless Coals	So. Ill., Pocohontas, Pennsylvania and W. Va.	Hocking, East Kentucky and West Va Splint
Prepared sizes...	$2.60—2.85	$2.85—3.35
Mine-run	2.40—2.60	2.60—3.00
Screenings	2.10—2.55	2.35—2.75

St. Louis—Prices per net ton f.o.b. mines are as follows:

	Williamson and Franklin Counties	Mt. Olive & Staunton	Standard
6-in. lump	$2.65-3.25	$2.65-2.80	$2.65-2.80
2-in. lump	2.65-3.00	2.65-2.80	2.25-2.50
Steam egg....	2.65-2.80	2.35-2.50	2.25-2.40
Mine-run	2.45-2.60	2.45-2.60	2.45-2.60
No. 1 nut.....	2.65-3.00	2.65-2.80	2.65-2.80
2-in. screen....	2.15-2.40	2.15-2.40	2.15-2.40
No. 5 washed..	2.15-2.50	2.15-2.35	2.15-2.35

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump & Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona	2.15	2.40	1.90
Black Creek, Cahaba.	2.40	2.65	2.15

Government figures.

Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

POWER

Vol. 47 NEW YORK, MAY 21, 1918 No. 21

Pointers to Success

PERHAPS one of the most convincing arguments in favor of education can be found in the large percentage of young men who are today filling the higher-up executive positions in all lines of business. While recently inspecting one of the largest central-station plants in New England, the writer was particularly impressed with the comparative youth of the executive personnel. Many of them were men from the ranks, who, by close observation and study, had fitted themselves for their present duties. Only three were college or university men with degrees. I asked the thirty-five year old superintendent of power, who has climbed the ladder by way of the boiler room, just how he had fitted himself for his position, and his reply is food for thought for many of the young fellows in the field today. He said:

"My heart and brain were in my work, and the best textbooks, papers and journals were my companions in most of my leisure time. I always solicited help in any problem from my fellow engineers, superiors and others who were able and willing to assist me. I had confidence in myself and never was content to remain at a standstill after I had made ready for the next step."

The secret of this man's success lay in the fact that he had made a decision early in his youth to have confidence in his ability to never stand still too long—to keep on climbing and to get help from the other fellows with which to boost himself up another rung on the ladder.

Look right about you among fellows you used to know. Some of them, no abler than you, are climbing, and what they are accomplishing you can accomplish. Studying alone—trying to teach oneself in spare time at home—is the hardest kind of work. Of course it is discouraging not to have assistance when you get stuck on some problem. Your studies can be lightened a great deal and made more interesting if you have the right kind of reading matter. The technical press is the workman's teacher, and some papers will even respond to appeals for help in understanding the principles of working problems.

Avail yourself of the privilege of laying your perplexities before some of the best men in the field, who will gladly help you through the pages devoted to plant problems. Often there are talks or lectures that you can attend, or perhaps there is an association of engineers to which you should belong and get some of the benefits of the discussions which take place. You will get some pointers at each meeting, and the personal contact with the local engineers is valuable. There are lots of problems to argue about, and this battle of wits will stimulate increased interest in your study of books and journals, for, when you get cornered in an argument, you will always look up the subject in the book or consult your trade journal, if you are a real engineer.

There are unlimited ways for you to train yourself for the bigger job if you are willing to sacrifice a portion of your time, energy and money. Nobody can push you ahead; your employer can open a path for you only when he is able to see increased value in your ability to handle the work. He may take a special sort of interest in you—but even this is of little help if he finds you are not training or assisting yourself. So it's up to you to make good. Many a man has been able to make himself so valuable that his services are always in demand, and this sort of man, you will always notice, is a close student of his calling.

Character, energy, brains, initiative and capacity for responsibility are the factors that make modern engineers command, instead of seek their positions. The envious attribute success to luck. Not every man can reach the top, for there are not enough places to go around. Some fellows soothe their minds with such thoughts, which are but lame excuses, for they are too lazy to study. They get just about so far and then plod along in a rut during their remaining years. The very sight of such men should stimulate a desire in you to avoid following in their path.

Contributed by C. H. Willey

Interconnected Power Systems of the South*

Hydro-electric systems of independent companies operating in five states are connected into one vast transportation system. These plants are mainly hydro-electric, but several steam stand-by plants are included. The United States Geological Survey has estimated the available power in the headwaters of the Appalachian Mountains at 2,800,000 hp., and the estimate for all the systems of the South is about 5,000,000 horsepower.

HYDRO-ELECTRIC power is a resource that will attract to a community a line of manufacturing that usually seeks cheap power as the prime requisite. The development of high-tension transmission systems has become common in many parts of the United States, but it was in the South that the logical and obvious thing was first done by interconnecting a number of systems with resultant advantages and economies. By this interconnecting of power plants the Southern States can boast a high-tension line approximately 1000 miles long from Nashville, Tenn., to Henderson, N. C. This ties together the hydro-electric systems of five companies operating in four states. In other words, all the great transmission systems of the South with the exception of that controlled by the Alabama Power Co. are interconnected. It is probably only a question of time until all properties will not only be interconnected but possibly owned and controlled by a master organization.

Among the advantages which follow from the interconnection of such systems none is greater than the improvement in the diversity factor. The difference of one hour in time between Henderson, N. C., and Nashville, Tenn., adds to the normal diversity factor of each system.

The United States Geological Survey has estimated the available power in the headwaters of the Appalachian Mountains at 2,800,000 hp. The estimate for all the systems of the South is about 5,000,000 hp. The Appalachian region has an enormous rainfall with a topography that is favorable to the development of low-head power plants. The illustration at the head of this article is typical of the Southern water powers. High heads as a rule do not exist and flumes and penstocks are little used. The absence of lakes in the region makes natural storage of water impossible.

Among the power companies in the United States and Canada having yearly outputs in excess of 100,000,000 kw.-hr., there are three Southern concerns, according to data given in the *Electrical World*, March 23, 1918.

System	Peak Load, Kw.	Yearly Output, Kw.-Hr.	Yearly Load Factor Per Cent.
Tennessee Power Co..	85,200	547,945,475	73.41
Alabama Power Co...	58,250	289,715,125	56.7
Georgia Railway & Power Co..	78,200	258,607,882	

FIG. 1. INTAKE DAM AT TALLULAH FALLS, GEORGIA RAILWAY AND POWER CO.

---

*"Metallurgical and Chemical Engineering."

The properties owned by the Alabama Power Co. include several sites on the Coosa River, one site on the Tallapoosa River, one on Little River, and sites at Muscle Shoals on the Tennessee River. On these sites approximately 500,000 hp. can be developed. The hydro-electric stations of the company at present in operation are located at Lock 12 on the Coosa River, where a head of 68 ft. is available, and at Jackson Shoals, on Choccolocca Creek, where a head of 22 ft. is available. Sixty-cycle three-phase energy is generated at 6600 volts in the Coosa River plant and 2300 volts in the Jackson Shoals plant. The company has at present in operation 180 miles of steel-tower transmission lines equipped with suspension-type insulators and 00 stranded copper cable for transmitting energy at 110,000 volts to four substations over private rights-of-way. The substations are situated at Gadsden, Anniston, Jackson Shoals and Magella, near Birmingham. Substations operated at 22,000 volts are in operation at Talladega, Leeds, Lovick, Alexander City, Gadsden and Attalla. The high-tension substations are of the outdoor type. It is the purpose of the company to standardize these as to size and type on 3000-, 6000 and 10,000-kv.-a. ratings. At present 45,300 kv.-a. is installed in the four substations. The company has 25,000 kw. of available steam auxiliary apparatus, comprising a 12,500-kw. steam-turbine station at Gadsden[1], containing two 6250-kv.-a. units, and a 15,000-kw. steam-turbine and reciprocating-engine plant. With the available steam auxiliary of 25,000 kw. operating as required and furnishing approximately 7.55 per cent. of the total kilowatt-hour output, 62,400 kw. of primary power at 50 per cent. load-factor can be delivered as soon as another hydro-electric unit is installed. The Anniston substation is a switching station for two 110,000-volt lines which pass through it. The Jackson Shoals substation is also a switching station for three 110,000-volt circuits from the north, south and west. The Magella substation will have an ultimate rating of 67,000 kilowatts.

FIG. 2. COLUMBUS POWER CO.

FIG. 4. YADKIN RIVER POWER CO., BLEWETT FALLS, N. C., HYDRO-ELECTRIC PLANTS FROM NORTHEAST

Carolina Power and Light Company

The Carolina Power and Light Co., in addition to the property owned and directly operated, also controls the Yadkin River Power Co. and the Asheville Power and Light Co.

The last-named company operates the electric light and power service in Raleigh, Goldsboro, Henderson, Oxford, Sanford and Jonesboro, furnishing electric light and power service for manufacturing properties in Fayetteville, Clayton, Smithfield, Selma, Franklinton, Pine Level and Cumberland. It also supplies under contract the entire requirements of the municipal electric light and power systems in Smithfield, Selma and Clayton and all the privately owned electric light and power systems in Franklinton and Pine Level. The company operates 188 miles of high-tension transmission line connecting two hydro-electric and three steam plants with distributing systems in all the communities served. The larger of the hydro-electric plants is located at Buckhorn Falls on the Cape Fear River and has an installed capacity of 3300 hp. The smaller is a plant of 530 hp. on the Neuse River near Raleigh. The company has also in reserve a modern steam plant of 5000 hp. capacity at Raleigh, one of 950 hp. at Goldsboro and one of 300 hp. at Henderson. It operates nine substations with an aggregate capacity of 23,000 horsepower.

The properties of the Carolina Power and Light Co,

FIG. 3. THE GREAT FALLS PLANT OF THE SOUTHERN POWER CO.

---

[1] Gadsden Steam Power Plant, "Power," Aug. 4, 1914.

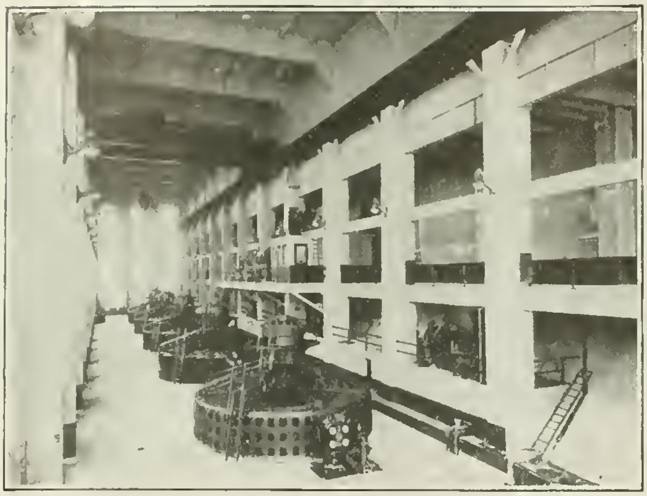

FIG. 5. 90,000-HP. GENERATORS—COOSA RIVER INTERIOR VIEW LOCK NO. 12 POWER HOUSE

are situated in the heart of the North Carolina industrial district. A large part of the electric energy sold by the company is supplied to cotton mills, cotton gins, cottonseed-oil mills, fertilizer works, veneer mills, furniture factories, machine shops, brick plants and other manufacturing establishments, and to municipalities for pumping water.

The Yadkin River Power Co. owns and operates a hydro-electric development on the Yadkin River, at Blewett Falls, near Rockingham, N. C., with an initial installed capacity of 32,000 hp. It has in operation 184 miles of high-tension transmission lines, located on private right-of-way, and 49 miles of distributing lines, five substations, with a total capacity of 4100 hp.; lighting and power systems in Rockingham, Hamlet, Wadesboro and Lilesville, N. C., and Cheraw, S. C., and an electric-power service in Lumberton, N. C., The transmission lines are connected with those of the Carolina Power and Light Co. and the Southern Power Co. The power station at Blewett Falls is one of the most modern in the South. It is 285 ft. long by 70 ft. wide, three stories in height, and is built of steel and brick with concrete foundations, floor and roof. The dam is of solid concrete construction. It has a total length of 1470 ft. and a maximum height of 50 ft. The dam has created a reservoir eight miles in length with a total area of 2500 acres. The station was placed in regular operation in June, 1912.

Like the properties of the Carolina Power and Light Co., those of the Yadkin River Power Co. are situated in the Carolina cotton-mill district, and a large part of the electric energy sold by the company is supplied to cotton mills, cotton gins and cottonseed-oil mills. It also supplies power to numerous other industrial plants, such as fertilizer works, veneer mills, furniture factories, brick plants and railroad shops, and to municipalities for pumping water.

Columbus Power Company

The Columbus Power Co. has three hydro-electric developments on the Chattahoochee River, two at Columbus having an aggregate rating of 9000 kv.-a. and one at Goat Rock, 15 miles north of Columbus, having 13,750 kv.-a. installed, making the total available 22,750 kv.-a. The City Mills development at Columbus comprises five generators with an aggregate rating of 1000 kw., the head being 10 ft. The North Highlands development has six generators, with an aggregate rating of 6900 kw., and waterwheels operating under a head of 42 ft. The Goat Rock development, where a head of 72 ft. is available, has three generators, two of which are rated at 3750 kw. and the other at 5000 kw. Three-phase 60-cycle energy is generated at 5500 volts and 11,000 volts. Two 4000-kw. transformers step up the potential to 66,000 volts for transmission. A 11,000-volt line on wooden poles with pin-type insulators connects the Columbus and Goat Rock properties, and a 60-mile steel-tower line equipped with suspension-type insulators and operating at 66,000 volts extends from Goat Rock at Newnan. There is 18 miles of wooden-pole line operating at 11,000 volts connecting Newnan and Hogansville. Four main substations are connected to the system: One at Columbus, rated at 1600 kw.; one at West Point, rated at 1875 kw.; one at La Grange, rated at 1875 kw.; and the fourth at Newnan, rated at 4000 kw. The system operates continuously on a 40 per cent. load-factor basis, and auxiliary steam-generating apparatus of the capacity of 3000-kw. turbo-generators is available. Provision is made for the transfer of 3000 kw. between the Columbus Power Co.'s system and the system of the Georgia Railway and Power Co.

FIG. 7. DUNLAP PLANT, GEORGIA RY. AND POWER CO.

FIG. 6. THE ROCKY CREEK PLANT OF THE SOUTHERN POWER COMPANY

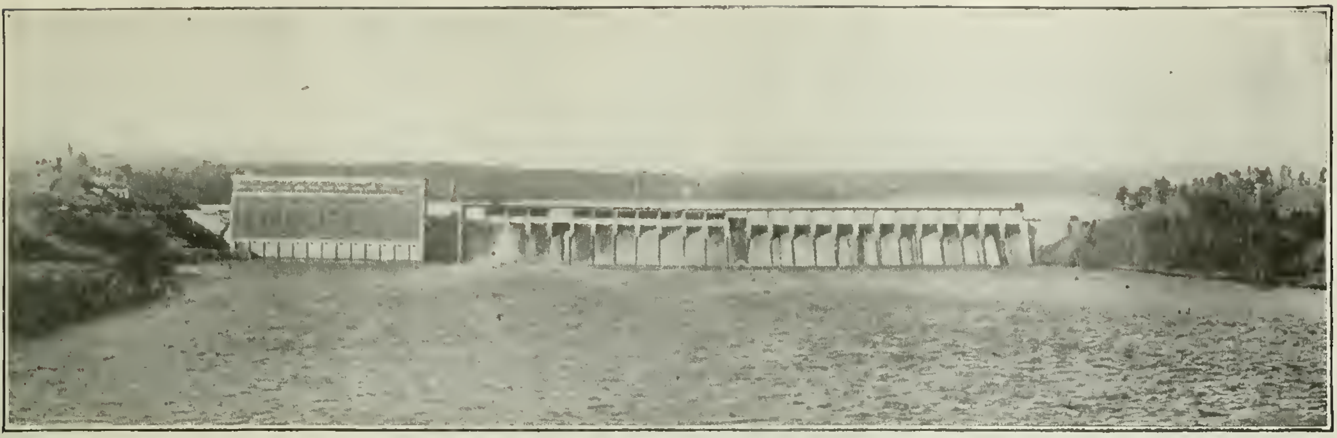

FIG. 8. LOCK 12. HYDRO-ELECTRIC PLANT—DOWNSTREAM VIEW

GEORGIA RAILWAY AND POWER COMPANY

The present coal-supply conditions emphasize the importance of existing water-power generating plants and the vital need of additional developments.

The 100,000-hp. plant of the Georgia Railway and Power Co. at Tallulah Falls[2] was barely finished when the rapid increase in the demand for hydro-electric power forced the company to undertake the construction of additional water-power developments, which, when completed, will nearly double the present capacity of its existing water-power plants.

The growth of the business in the last six years is shown in the following table of yearly outputs in kilowatt-hours:

1912	68,400,642	1915	179,976,596
1913	80,763,025	1916	211,872,638
1914	145,684,803	1917	258,607,802

This shows an increase in that period of nearly 300 per cent.

The water power furnished by the company to its customers in 1917 would have required approximately 475,000 tons of coal if generated by them by steam. The additional water power which it is estimated will be generated at the new plants now under construction, and which has already been largely sold, will take the place of and save approximately 400,000 tons of coal annually—a total combined saving of approximately 875,000 tons of coal per annum.

The new developments now being constructed are as follows:

The Burton storage reservoir, to be in service by the end of year 1918, is three miles north of the present Mathis storage reservoir and will flood approximately 3000 acres of land. It requires the construction of a dam 700 ft. long and 100 ft. high of cyclopean masonry. The reservoir will store approximately five billion cubic feet of water. The water contained in this reservoir, exclusive of the average flow of the river, will produce at the Tallulah Falls and Tugaloo generating plants 65,000,000 kw.-hr. and will increase the annual capacity of those plants to that extent. This reservoir will also make possible the equalization of the river flow, or in other words, the even distribution of all available rainfall run-off from its contributary watershed throughout every month in the year, the stored water being drawn out for use in the dry months and replaced in the wet season. The water that can be stored in this reservoir is equivalent to the available energy in 130,000 tons of coal.

The Tugaloo development is about two miles below the present Tallulah Falls power house on the Tugaloo River where the Tallulah and the Chattooga Rivers come together and form the Tugaloo. The water available at this point for power purposes comes from both the Tallulah and the Chattooga Rivers. The average flow of the river, including the effect of the Mathis storage reservoir, it is estimated will produce at this plant approximately 120,000,000 kw.-hr. It will require only 1½ miles of transmission line to connect this development with the present Tallulah Falls transmission lines. The Tugaloo dam of cyclopean masonry is

---

[2] Tallulah Falls Development, "Power," Jan. 27, 1914.

FIG. 9. LOCK 12. HYDRO-ELECTRIC PLANT—UPSTREAM VIEW

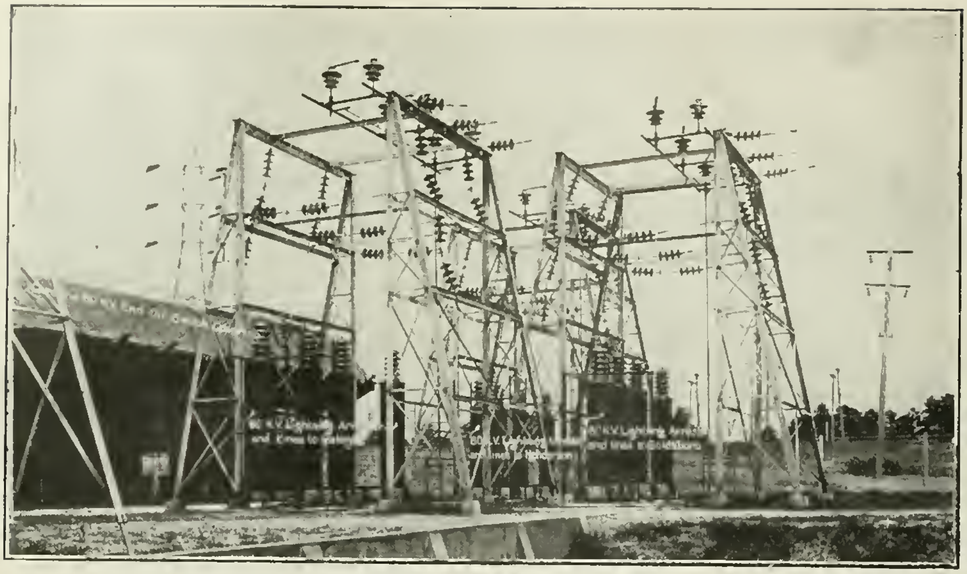

FIG. 10. METHOD (N. C.) OUTDOOR SUBSTATION LOOKING NORTH. CAROLINA POWER AND LIGHT CO.

800 ft. long and 140 ft. high. The Tugaloo plant will develop approximately 65,000 hp., and it is estimated that two years time will be necessary in which to complete it.

The Tallulah Falls power plant was constructed and designed for six units of 12,000 kw., or about 17,000 hp. each. Five units are now installed. The sixth has been ordered and will be ready for service some time during the summer of 1918.

Contracts were let for all the required equipment for the three developments during the summer of 1917 and construction is now actively under way.

The estimated total cost of this construction is $5,000,000. The necessary financing to carry on the work was completed in June, 1917. The company was fortunate in this respect because the war has since brought such changed financial conditions that the necessary capital could not be secured at the present time and this has been continuously true since the financial arrangements were concluded.

The Georgia Railway and Power Co. upon completion of the plants now under construction will have waterpower plants of approximately 200,000 hp. developed and in service. The company controls approximately 300,000 undeveloped horsepower in addition, or a total developed and undeveloped of approximately 500,000 horsepower.

A large part of the power generated by the company is used by enterprises making war materials or supplies necessary to the successful prosecution of the war. This shows how doubly vital it is in war times that money for such developments should be available. It also points the lesson that many of us appreciated years ago; namely, the necessity of a broad and generous policy on the part of the Government in the development of the water powers of the nation. Water power should be provided to meet the increasing demand due to the war. But war conditions have made money unobtainable through the usual banking channels. From now on and as long as present conditions exist such developments cannot be made unless the National Government will furnish the needed capital with which to carry on the work.

The French government realized early in the war the vital need of largely increasing the available power for industrial purposes from other sources than coal and is now constructing water-power developments in Southern France on a large scale under the direction of an American engineer.

The power actually furnished by the Georgia Railway and Power Co. in 1917, if generated by its customers by steam, would have required 11,875 cars of coal of 40 tons capacity each, and the estimated power which will annually be generated by the plants now being constructed, will be the equivalent of 10,000 cars of coal of 40 tons capacity each additional, or a combined saving in coal consumption per annum of 21,875 cars of coal of 40 tons capacity each, or a total of 875,000 tons. If the remaining 300,000 hp. of undeveloped water power

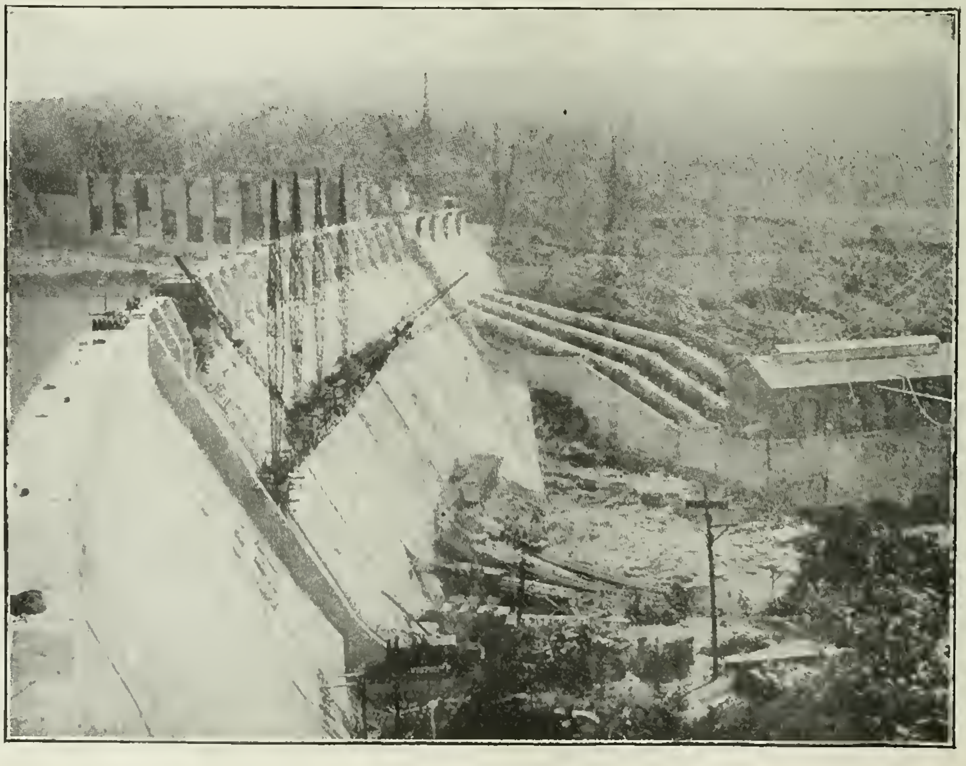

FIG. 11. THE TALLASSEE POWER CO., YADKIN RIVER, BADIN, N. C.

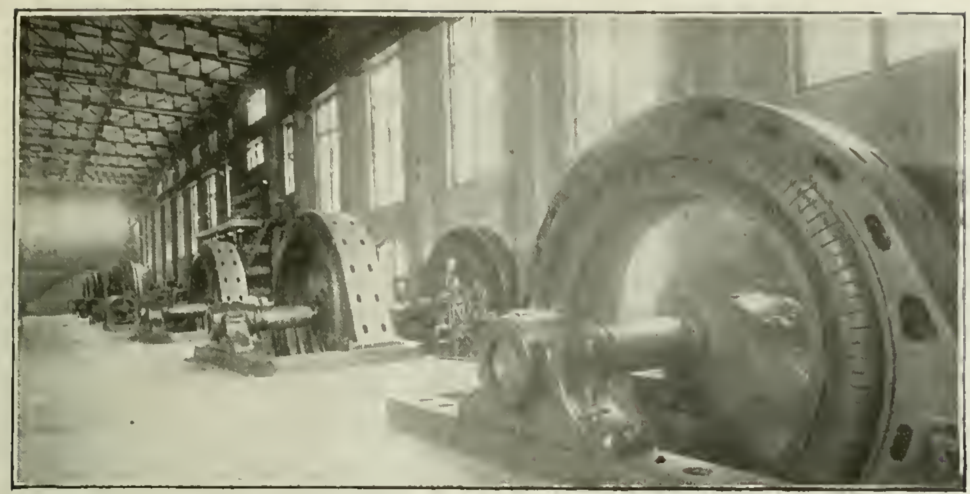

FIG. 12. YADKIN RIVER POWER CO. THREE 4500 Kv.-A., THREE 6000 Kv.-A. 4000 VOLT 60 CYCLE G. E. GENERATORS

controlled by the company could be developed and put to work, the saving would be two and one-half times as great, or a total of 54,687 cars of coal of 40 tons capacity each, or 2,187,480 tons of coal conserved with all its collateral economies.

If capital were now available for the construction of the necessary generating plants sufficient to utilize the undeveloped water power controlled by the Georgia Railway and Power Co., and the National Government would bring about the electrification of the steam railroads, all the important railroad mileage in Georgia would be operated by electric power generated by that company. The operating expenses of the railroads themselves would be materially reduced, their service much improved, and in addition the coal now consumed by them conserved, and the present regular business of the company supplied and developed as at present. This under present and past conditions is worth while.

SOUTHERN POWER COMPANY

The Southern Power Co. is connected to the Carolina Power and Light Co. at a point between Durham and Raleigh, N. C., and with the Georgia Railway and Power Co. of Tallulah Falls. The location and maximum ratings of the company's various stations are given in the accompanying table.

Electricity is generated at 2200, 6600 and 11,000 volts, three-phase, sixty-cycle, there being one 8000-kv.-a. 2300-volt and two 8000-kv.-a. 11,000-volt steam-driven generators, twenty-two 3000-kv.-a. 3000-volt generators, three 7800-kv.-a. 6600-volt generators, four 900-kv.-a. and 750-kv.-a, 11,000-volt generators. The last 33 units are of the water-wheel type. There are also connected to the system 65 high-voltage transformers having an aggregate rating of 169,400 kv.-a. The lines of the company cover a territory of 300 miles in a northeasterly and southwesterly direction and 100 miles in a northwesterly and southeasterly direction. The first transmission system of the company is designed for 11,000 volts. With the expansion of the company and its activities, a 44-000-volt transmission system was built, and all of the recent transmission lines erected by the company have been designed for 100,000 volts. All lines are looped in together, and the 11,000-volt and 100,000-volt systems are tied together with tie-in transformers. Aluminum and copper are both used for conductors, the size ranging from No. 4 solid copper to No. 000 stranded. By far the greatest amount of the lines are of No. 00 copper stranded and No. 00 equivalent aluminum stranded. This is run on both steel towers and wooden poles with pin-type and suspension-type insulators, depending upon the voltage. There are 103 substations connected to the system, con-

DATA ON SOUTHERN POWER COMPANY'S STATIONS

Greenville, S. C. (steam)	8,000 Kv.-a.	
Greensboro, N. C. (steam)	8,000 Kv.-a.	
Mount Holly, N. C. (steam)	8,000 Kv.-a.	

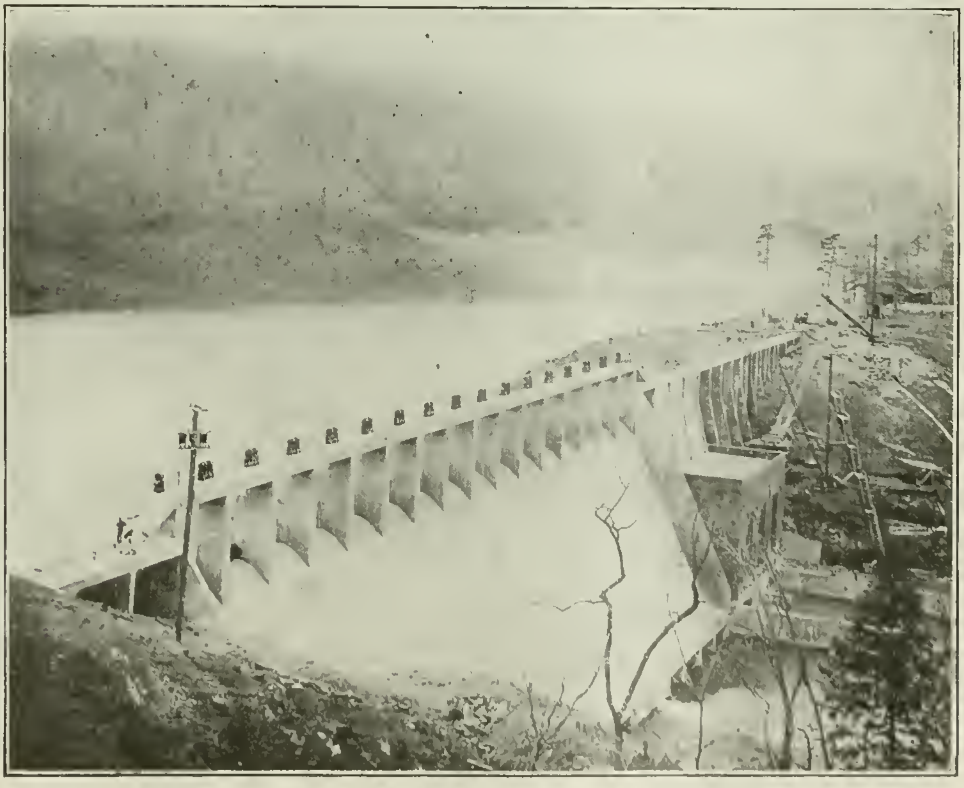

FIG. 13 MATHIS DAM, GEORGIA RAILWAY AND POWER CO.

FIG. 14. YADKIN RIVER POWER CO., BLEWETT FALLS, DAM AND POND

taining 352 transformers, with an aggregate rating of 241,162 kv.-a.

The circuits of the Southern Power Co. are connected on the north with those of the Carolina Power and Light Co. with two 100,000-volt lines. The amount of power that can be transferred is limited only by the carrying capacity of these lines, as no transformers are required in order to effect this connection. On the south the Southern Power Co.'s system is connected with that of the Georgia Railway and Power Co. of Tallulah Falls, with two 100,000-volt lines, and the power which can be transferred between the two companies at this point is limited only by the carrying capacity of the lines.

It should be pointed out that the rating of the hydro-electric stations of the Southern Power Co. is based upon the continuous rating for the continuous amount of 12-hour power which the station can generate for eight months in the year. The company maintains three 8000-kv.-a. turbo-generator steam plants for emergency and supplementary service. The fires under the boilers are banked, and all three stations can be got under way to feed energy to the lines within fifteen minutes.

TENNESSEE POWER CO.

The present hydro-electric stations owned and operated by the Tennessee Power Co. are as follows:

Ocoee No. 1, located in Polk County at Parksville, Tenn., on the Ocoee River, approximately 50 miles from Chattanooga. The equipment in this plant consists of five horizontal direct-connected waterwheel-driven generators, each one having a capacity of 3750 kw., the total station capacity being 18,750 kw. The dam at this plant backs up the Ocoee River, forming a lake approximately eight miles long. Sufficient water is impounded to operate the station over a period of two or three weeks during reduced stream flow.

Ocoee No. 2,[3] located in Polk County on the Ocoee River, about ten miles east of Parksville. This plant is equipped with two horizontal waterwheel-driven generators, each having a capacity of 7500 kw., the total capacity of the station being 15,000 kw. This plant uses the stream flow from the Ocoee River, which is diverted by means of a low dam, five miles above the power station, from which the water is conveyed by means of a flume to a forebay above the power house. The operating head at this plant is 255 feet.

Great Falls Station, at the northwest corner of Warren County, about halfway between Nashville and Chattanooga. This plant uses the flow of the Caney Fork and Collins Rivers. Just below the confluence of the two rivers a low concrete dam diverts the two streams, which are conveyed to the waterwheel by means of a tunnel and penstock. The plant is equipped with one vertical waterwheel-driven generator, the capacity being 9750 kilowatts.

Hales Bar,[4] on the Tennessee River about 20 miles west of Chattanooga. This plant is equipped with fourteen 3000-kw. vertical turbines, the total capacity of the

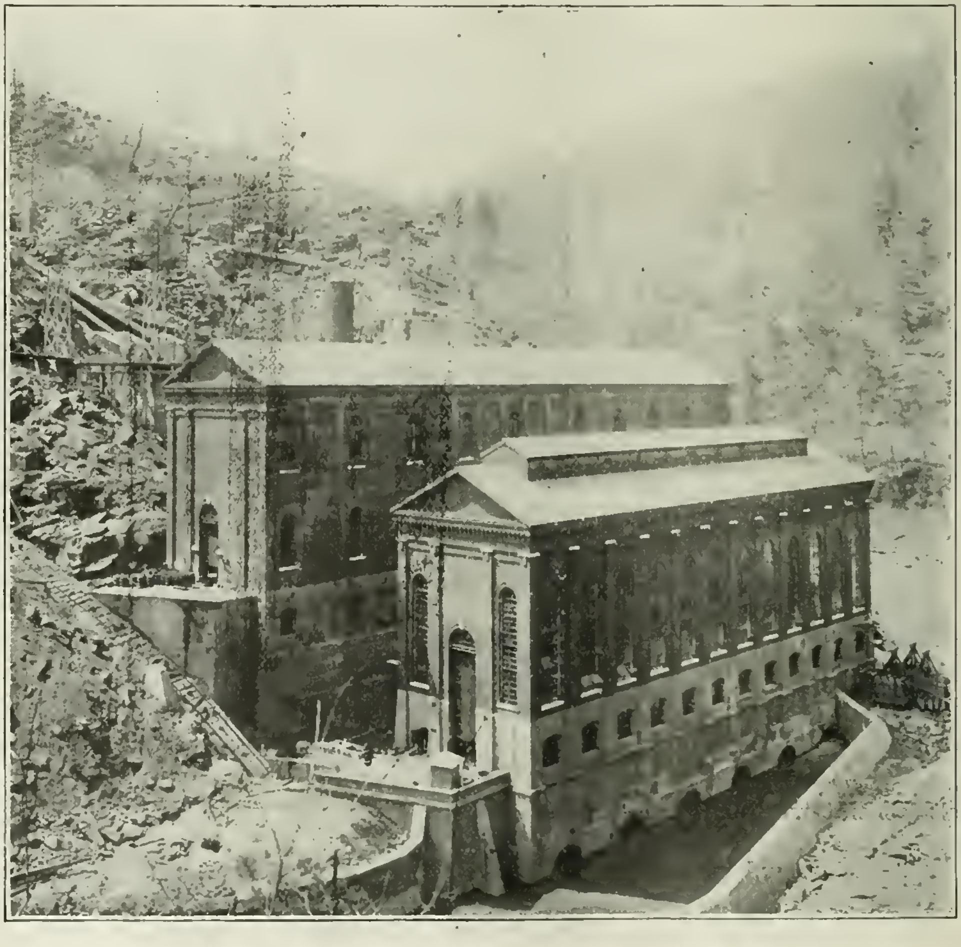

FIG. 15. TALLULAH FALLS POWER HOUSE, GEORGIA RAILWAY AND POWER CO.

[3] Completion of the Hales Bar Works, "Power," Dec. 2, 1913.

[4] Hydro-Electric Plants of the Tennessee Power Co., "Power," May 17, 1914

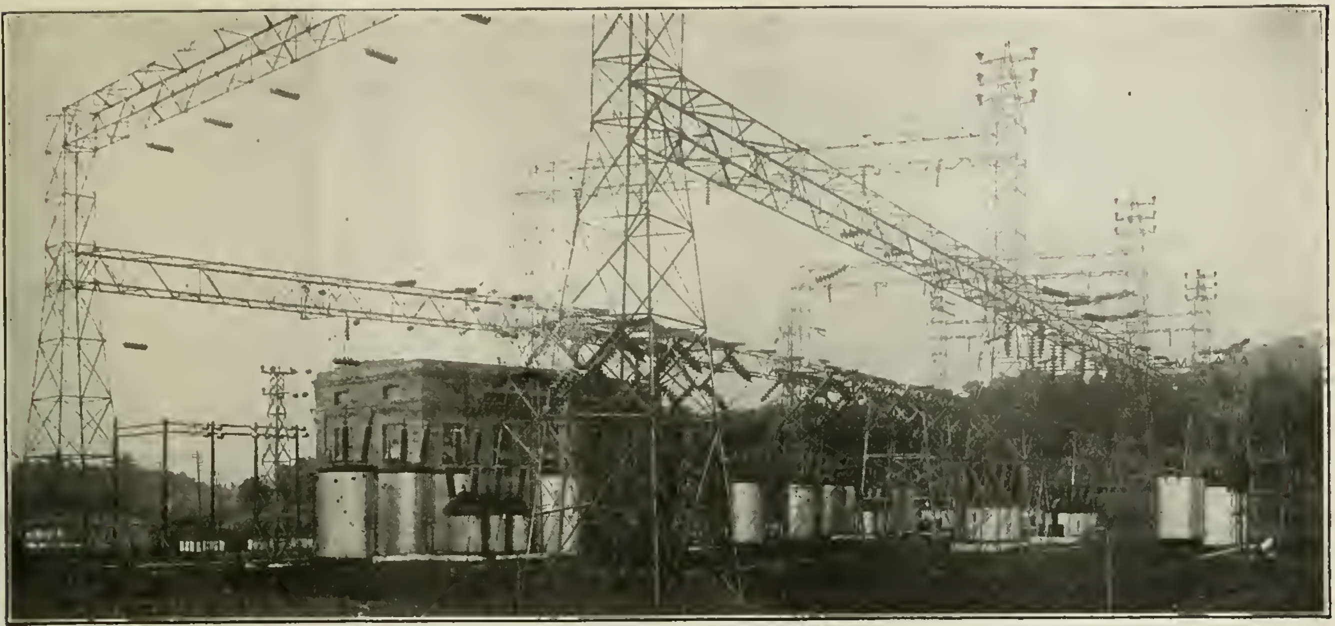

FIG. 16. SUBSTATION—ALABAMA POWER CO., COOSA RIVER HYDRO-ELECTRIC PLANT

station being 42,000 kw. The concrete dam across the river at the power-house site backs up the water and makes the river navigable to Chattanooga. The spillway is 1200 ft. long. The dam is of necessity provided with a boat-lock which is operated by the Government.

The combined capacity of the present hydro-electric stations is 85,000 kilowatts.

Additional developments have been considered, and rights obtained for three more stations on the Ocoee River, to be known as Ocoee Nos. 3, 4 and 5. The additional capacity from these three stations will be in the neighborhood of 35,000 kilowatts.

The Tennessee Power Co. has an arrangement with the Chattanooga Railway and Light Co., the Nashville Railway and Light Co. and the Knoxville Railway and Light Co. whereby the steam plants at these three cities may be operated at the direction of the Tennessee Co. to supplement the output from the hydro plants during low water. The capacities of the steam stations are as follows:

	Kilowatts
Chattanooga	5,000
Nashville	15,000
Knoxville	4,000
Total	24,000

The Tennessee Power Co. generates the electrical energy used in Chattanooga, Nashville, Knoxville and a large number of the small cities in eastern Tennessee. In addition it supplies power to the Aluminum Company of America at Maryville, Tenn., 16 miles south of Knoxville, and also to the American Zinc Co. at Mascot, Tenn., 15 miles northeast of Knoxville. The total transmission-line mileage of this system is approximately 600.

The rates for electrical energy are in accordance with the following tabulation:

A fixed charge of $1.25 per month per kilowatt of maximum demand based on the highest fifteen minute demand during the month, but in no event shall the fixed charge be less than 60 per cent. of the total kilowatt capacity contracted for.

In addition to the above demand charge, the following kilowatt-hour charge for electrical energy consumed during the month:

	Kilowatt-Hours
4c. per kw.-hr. for the first	500
2c. per kw.-hr. for the next	1,000
1½c. per kw.-hr. for the next	1,500
1c. per kw.-hr. for the next	17,000
0.7c. per kw.-hr. for all over	20,000

A discount of 5 per cent. will be allowed upon all bills paid within ten days from their date.

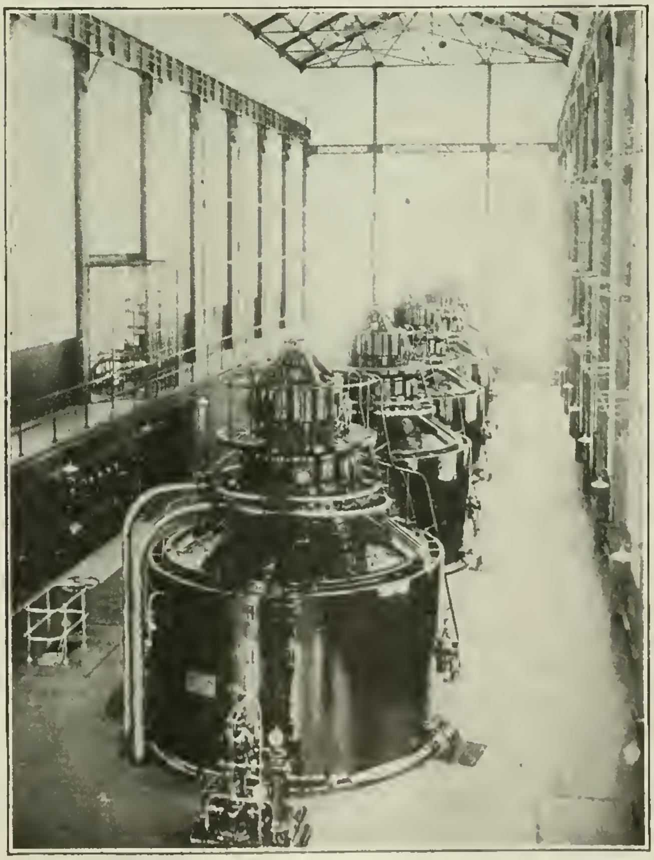

FIG. 17. GENERATORS, TALLULAH FALLS POWER HOUSE, GEORGIA RAILWAY AND POWER CO.

Coals of the United States

Gives the proximate analyses on the "as received" basis of typical coals of the United States. These analyses are given as the first of some articles on fuels, and types of stokers and furnaces best adapted to them, published to assist consumers who are confronted with the, to them, unusual combustion problems by reason of the zone system for the distribution of bituminous coal recently put into effect by the Fuel Administration.

TO GREATLY cut down transportation of coal on the railroads and to insure a larger supply of the Eastern bituminous coals to the states of the Atlantic Seaboard, the zone system for the distribution of bituminous coal has been put into effect by the Fuel Administration. Nearly all the states of the Middle West, heretofore large consumers of the high-grade coals of West Virginia and the East, must learn to burn the high-volatile, high-ash coals, also the lignites, in which the Middle West, North Dakota and Texas abound.

Power for May 14 gave full particulars about the zone system as it affects power plants particularly. See that issue to learn what coals are permitted to come into your state or zone. Knowing the coal you have been using, you can, by reference to the table here, find the chief differences between the coal or coals you now use and those you will hereafter use.

The analyses are selected from Bulletin No. 22 of the Bureau of Mines. The names on the same lines with the figures are those of the mines or towns.

The Electrical Study Course—Characteristic Curves of Shunt and Series Generators

The effects of varying the load on a shunt and a series generator are discussed, and the external characteristic curves shown.

ELECTRIC generators and motors act in certain ways under given conditions; for example, as the current is increased in the field coil of a shunt generator, the voltage will increase in value until the iron in the polepieces becomes saturated. Beyond the saturation point the voltage remains practically constant irrespective of the value of the current in the field coils. By plotting the volts at the armature terminals against the amperes in the field coils, as explained in the lesson in the Apr. 9 issue, the result will be a curve similar to that shown in Fig. 1.

Similarly, the effect of the load on the voltage of a generator may be shown in a curve. This is done by connecting a voltmeter across the armature terminals and an ammeter in series in the circuit, as shown in Fig. 3; and after adjusting the voltage to normal, say 110 volts, put a load on the machine of, assume, 30 amperes, as indicated in Fig. 4. This, as shown in the last lesson, will cause the voltage to drop at the armature terminals: First, owing to the resistance of the armature, and second, the current in the field coils will also be slightly reduced because of the decrease in volts at the armature terminals. Assume that the volts at the armature terminals decrease 1.5, this will leave $E_a = 108.5$ volts available at the load and will give point *a* on curve *A*, Fig. 2, which is obtained by taking the 30-ampere division at the base of the curve and running up vertically until it intersects the horizontal line running out from the 108.5-volt division, as indicated by the dotted lines.

If the load is now increased to 60 amperes, the volts at the armature terminals will further decrease, say to 107; then plotting the load current of 60 amperes against the voltage at the armature terminals, 107 volts, gives point *b* on the curve. Increasing the load to 90 amperes will cause the voltage to drop accordingly, or, as shown at point *c* on the curve, to be 105.5. Now, if the load is further increased, a corresponding decrease in voltage is obtained. However, it is evident that this process cannot keep on indefinitely, because if it did, eventually a point would be reached where an infinitely large current would be obtained on an infinitely small voltage.

What actually happens in a shunt generator is that the voltage decreases as the current is increased up to a certain value and then both volts and current decrease to zero or approximately so. This is shown on the curve; when the current has increased to 241 amperes, the volts have dropped to about 55. At this point, if the resistance of the circuit is further decreased to increase the current, the voltage and current begin to decrease and come back to zero, or theoretically so. However, on account of the residual magnetism in the polepieces maintaining a small voltage at the armature terminals, the volts and current will only approximate zero.

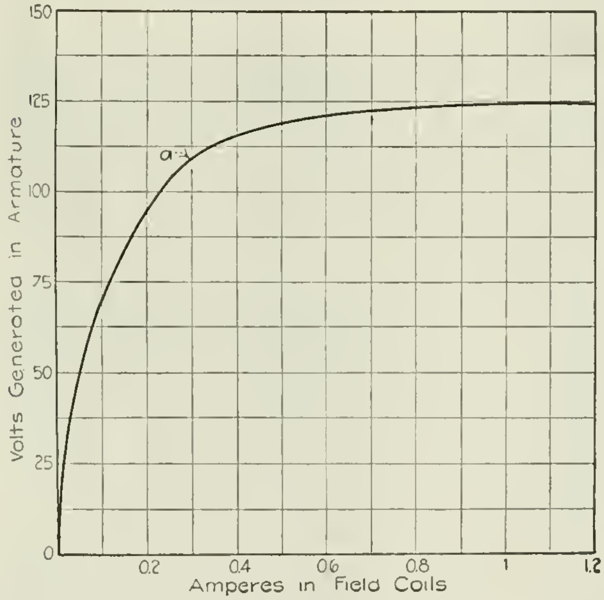

FIG. 1. DIRECT-CURRENT GENERATOR VOLTAGE CURVE

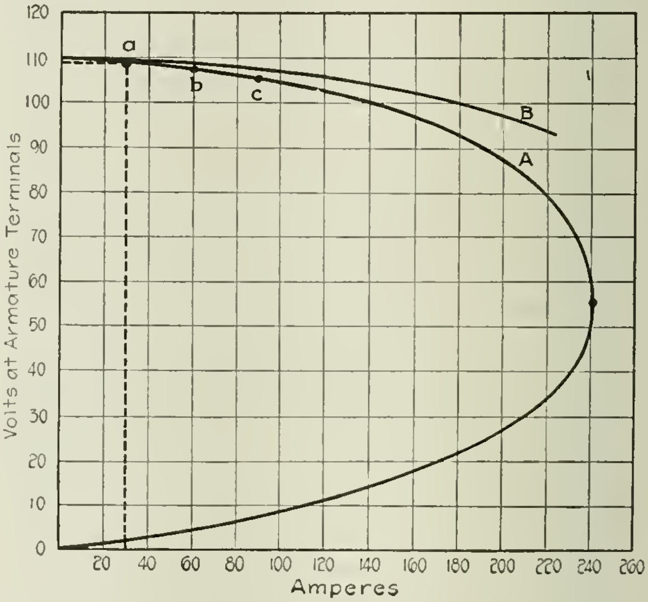

FIG. 2. LOAD-VOLTAGE CURVE OF SHUNT GENERATOR

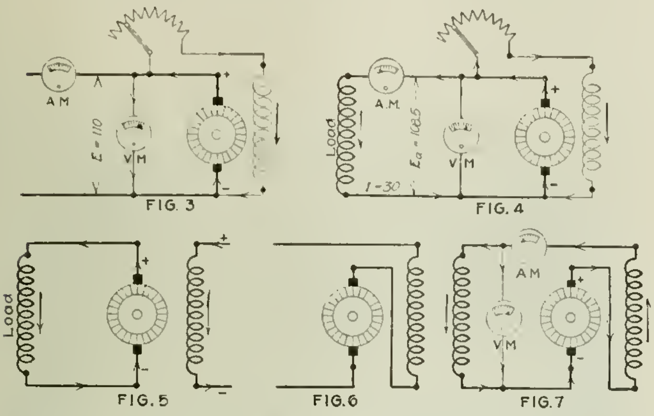
What has just been stated regarding the shunt machine indicates that if it was short-circuited, the voltage and current would drop to zero and no harm would be done. This is true of the self-excited shunt generator, but not of the other types, as will be seen in the following:

If the field coils of the shunt machine are energized from an outside source, as in Fig. 5, then the field current will be maintained constant irrespective of the load. Consequently, the voltage generated in the armature will remain practically constant, and the volts drop at the armature terminals will be due to the armature resistance only. Therefore, the volts at the armature terminals will not decrease so rapidly as when the field coils are connected in parallel with the armature. The resultant curve for a separate-excited shunt generator will be similar to the curve *B*, Fig. 2.

In the series-connected generator, Fig. 6, the machine cannot produce any voltage when it is disconnected from the load except that generated due to the residual magnetism in the polepieces. Consequently, at no load the voltage of a series machine is approximately zero, as against the shunt machine in which the voltage is at a maximum value at no load. By connecting a voltmeter and an ammeter to the series machine, as in Fig. 7, and taking readings for different loads, a curve will be obtained as in Fig. 8. It will be seen that the shape of the curve from zero to point *a* approximates the shape of the saturation curve, Fig. 1, from zero to point *a*.



FIGS. 3 TO 7. DIAGRAMS OF SHUNT-CONNECTED AND SERIES-CONNECTED GENERATORS

The series generator as its voltage builds up with the load has not only to produce pressure to cause the current to flow through the external circuit, but also through the armature and field windings. The volts drop in the armature and field windings varies as the product of the current in amperes and the resistance of the windings in ohms. However, the total voltage generated in the armature winding does not increase as the current in the field winding. Referring to Fig. 1, it will be seen that up to point *a* on the curve, the increase in volts is quite rapid as the field current is increased, but beyond this point the increase is very slow, being practically zero at the upper end of the curve. It is this latter fact that makes the voltage of the series generator decrease above a certain load.

In Fig. 8 the first 20-ampere load energizes the field coils to the extent that 50 volts is generated at the armature terminal. When the load is increased to 40 amperes, the volts only increase to about 73 and at 60 amperes about 91 volts, until at 130 amperes, the maximum, or 114 volts, is developed at the armature terminals. From this it is seen that the volts at the armature terminals increase rapidly at first, but that the increase becomes less for a given number of amperes increase until an increase in load does not cause the volts to become greater but less, as in this case, when the load is made higher than 130 amperes.

Now, if we assume the resistance of the armature and field windings to be 0.2 ohm, then with a 20-ampere load on the machine the volts drop will equal amperes × ohms, or 20 × 0.2 = 4 volts; that is, the armature is actually generating 54 volts when supplying 20 amperes to the external circuit, but 4 volts is used up to cause the current to flow through the armature and field windings; therefore, only 50 volts is available at the armature terminal. At a 60-ampere load the volts drop in the armature is 60 × 0.2 = 12 volts. Hence, the armature is generating a total voltage at this load of 91 + 12 = 103 volts. When the load has increased to 130 amperes, the volts drop in the armature is 130 × 0.2 = 26 volts, and there is generated 114 + 26 = 140 volts. However, 26 volts is used up in the machine's windings, consequently only 114 is available at the armature terminals. Assume that the load is increased from 130 to 180 amperes. Then, the drop in the armature will be 180 × 0.2 = 36 volts. Further assume that this increase of load only causes the total voltage to increase to 143.5. Then, the available volts at the armature terminals is 143.5 — 36 = 107.5. Hence, it is seen that the increased volts generated in the armature due to the increased load is not enough to compensate for the increased drop in the windings, and the available volts decrease with an increase in load. Hence, it is evident that the volts at the armature terminals on a series generator will increase in value with an increase in load until the iron in the magnetic circuit is near saturation; beyond this point the volts begin to decrease with an increase of load.

The curves, Figs. 2 and 8, are sometimes referred to as external characteristic curves of the generator, from the fact that they are plotted from conditions existing outside the machine. If the voltage values existing in the armature windings were used in the curves, we would have to add the volts drop in the armature at the different loads to the voltage at the brushes corresponding to these loads, which would have given a higher pressure than that indicated on the curves in the figures. A load-voltage curve plotted by using the total voltage generated in the armature instead of that at the brushes is called an internal-characteristic curve.

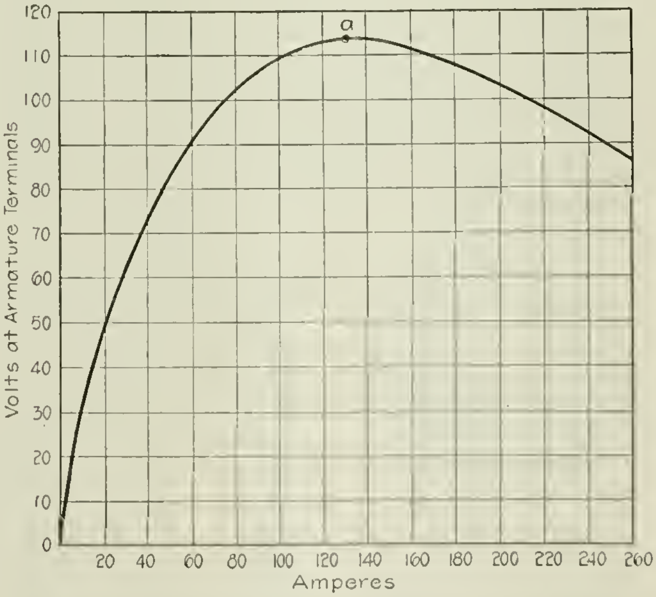


FIG. 8. LOAD-VOLTAGE CURVE OF SERIES GENERATOR

The problem given in the last lesson was: "In transmitting 540 amperes over a circuit 425 ft. long one way, there is a drop of 16.5 volts in the line. How large are the conductors in cross-section? How much will the conductors have to be increased in size to reduce the line drop to 10 volts?"

The size of the conductors is obtained by the formula,

$$Cir.mils \quad \frac{21.7DI}{E_d} = \frac{21.4 \times 425 \times 540}{16.4} = 299{,}469$$

which is approximately a 300,000-cir.mil conductor. The size of a conductor that would cause only a 10-volt drop under the foregoing conditions can also be determined by the circular-mil formula, or in this case,

$$Cir.mils = \frac{21.4 \times 425 \times 540}{10} = 497{,}130$$

or approximately 500,000 cir.mils. Then the size of the conductor would have to be increased 500,000 — 300,000 = 200,000 cir.mils.

A voltmeter has 12,000 ohms resistance, and when connected to two points of a circuit reads 36 volts. Find the current taken by the instrument. If 3.6 amperes is passing through the section of the circuit that the instrument is connected across, find the resistance of the section.

If the resistance of a voltmeter is 15,000 ohms and when connected across a given circuit 0.01 ampere flows through it, does the instrument indicate the correct voltage of the circuit if the needle points to 140 on the scale?

Dry Crown-Sheet Firebox Boiler

By S. P. Black

The illustrations show a type of boiler that most readers would say was unfeasible if they were asked their opinion as to utility and safety without previous knowledge that hundreds of these boilers have been used for years with no disastrous results. I remember being in one of the large boiler shops of the Middle West when the specifications for one of these boilers came in and figures were asked regarding its construction. Our opinion at that time was that whoever knew no better than to design such a boiler, expecting it to work in safety, needed a guardian and that would be putting it mildly.

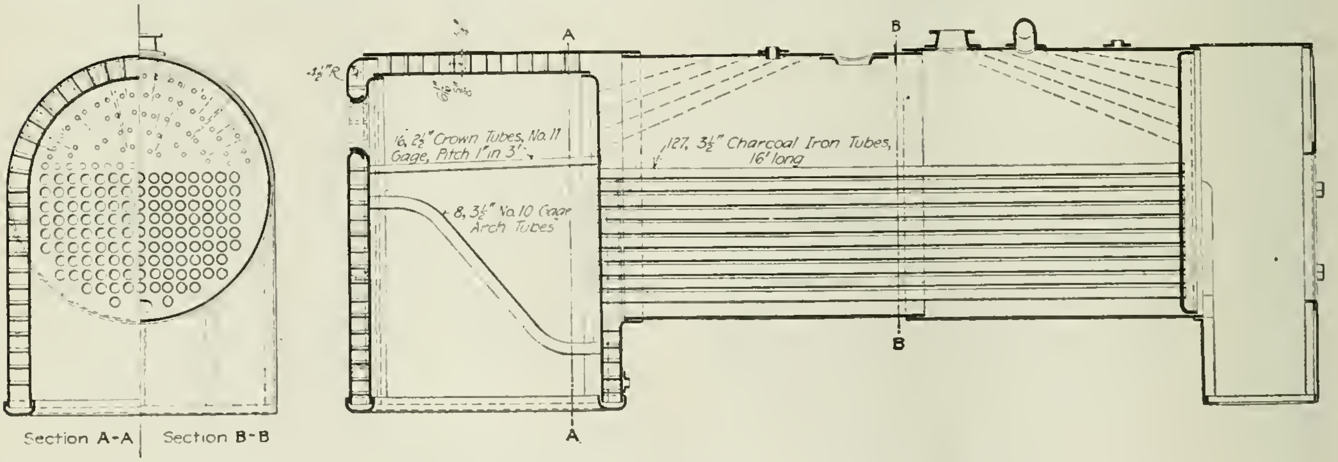

FIG. 2. SECTION THROUGH DRY CROWN-SHEET BOILER

An examination of Fig. 2 would at first suggest that the design is a contradiction of all known boiler rules in the deliberate use of a dry crown-sheet, one that is not covered by water; for it may be observed that the water-leg, a 6-in. space, is continued completely under the wagon top, and that the water level scarcely reaches within 18 in. of the top of the boiler as would be indicated by Fig. 2.

We are all forced to alter our preconceived opinions somewhat at times, and after finding this type of boiler in use and watching it under operation, I have gotten rid of a pre-established prejudice and dislike, as I have known them to be operating under severe conditions for about fifteen years.

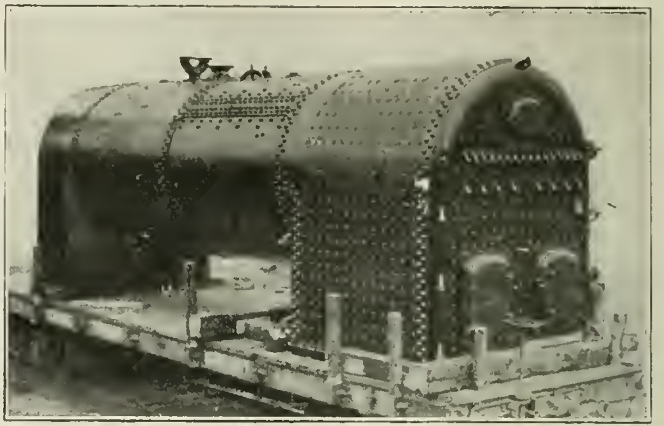

FIG. 1. EXTERIOR OF DRY CROWN-SHEET BOILER

Most of us can remember the popular fallacy and general belief not long since prevalent of red-hot crown-sheet, low water, turning on the feed and an explosion from sudden generation of steam. We used to believe that cold water on a red-hot crown-sheet would generate sufficient steam to cause an explosion, but experiments have proved the contrary and have shown that it was a difficult matter to bring about an explosion under such conditions.

In the boiler shown in Fig. 1, although it was not designed to be foolproof and even though the crown-sheet is at all times bare of water and entirely dry, such a thing as burning the crown-sheet has never occurred to my knowledge. Furthermore, this type of boiler is one that has the reputation of being impossible to burn, low water not affecting it until the water gets below the arch tube and exposes the upper portion thereof, at which time the tubes will blow out. This boiler was designed for 175 lb. pressure, a fairly high pressure for this type of boiler.

Supporting Effect of Boiler Heads

BY NEIL M. MACDONALD

Should the strength of the unsupported head be added to the strength of the stays to find the allowable pressure in a boiler? The author answers the question in the negative.

THE tendency of modern engineering practice is toward larger boiler units and high pressures. This tendency makes it imperative that serious consideration be given to the bracing and stay-bolting of the boiler surfaces. A number of engineers contend, no doubt without giving the subject proper consideration, that the strength of the braces or stay-bolts should be added to the strength of the sheet which they presumably support, and that the sum of these two values should be taken as the strength of that portion of the boiler. At first sight this theory may appear logical, but careful consideration clearly illustrates the fallacy of the contention.

There are four boiler surfaces which will be considered one by one, to indicate wherein the foregoing method of figuring is erroneous. The first case is the braced portions of the heads of a horizontal return-tubular boiler and particularly that portion above the tubes. Assume, by way of illustration, a 72-in. by 18-ft. horizontal-tubular boiler having a distance of 26 in. between the top of the tubes and the shell plate. The area to be braced in this case is the area of a segment inclosed by lines drawn 3 in. from the shell and 2 in. from the tubes, or an area of 936 sq.in.

First find the strength of the unbraced flat head. There is no authentic formula for figuring accurately the strength of an unbraced flat head, and what is known of the subject is based on theory combined with a few practical experiments. However, as absolutely accurate results are not essential for the purpose of this discussion, the strength of the unstayed head will be calculated in accordance with Nichols' formula, which is based on his experiments and is

$$P = \frac{T \times S \times C}{A \times F}$$

in which

P = Safe working pressure, in pounds per square inch;

T = Thickness of plate, in inches;

S = Tensile strength of plate, in pounds per square inch;

C = Constant = 10;

A = Area to be stayed, in square inches;

F = Factor of safety = 8.

Assuming that the boiler head is ½-in. thick and that the material has a tensile strength of 55,000 lb. per sq.in., and substituting these values in the formula,

$$P = \frac{\frac{1}{2} \times 55{,}000 \times 10}{936 \times 8} = 37 \textit{ lb. per sq.in. nearly}$$

The bursting pressure is, then, 37 × 8 = 296 lb. per sq.in.

Now, in accordance with the foregoing erroneous theory, if the boiler was to be designed for a safe working pressure of 125 lb. per sq.in., it would only be necessary to add bracing good for 125 — 37 = 88 lb., or the difference between the strength of the unbraced head and the strength required. Following this theory, if the factor of safety on the unbraced head was 8 and on the braces 6, the bursting pressure of the braced head would be 37 × 8 + 88 × 6 = 824 lb. per sq.in. This is absolutely wrong, and the attempt will be made to prove, by illustration, that the real bursting pressure of the head is only the value of the strongest portion, which in this case is the braces, and is 88 × 6 = 528 lb. per sq.in. The safe working pressure is the bursting pressure divided by the factor of safety, or 528 ÷ 6 = 88 lb. per square inch.

To illustrate the fallacy of the theory, assume a solid stone wall capable of withstanding a pull of 1000 lb., and a second solid stone wall directly oposite the first one, able to withstand any pull up to 296 lb. It is assumed that these walls are so constructed that if a pull of 296 lb. is applied to the stronger wall, it will not be affected, but if the same pull is applied to the weaker wall, it will collapse.

Now, join the two walls by a rope, fastened so that it cannot slip, and capable of standing any pull up to 528 lb. Apply a pressure between the two walls tending to push them apart and strain the rope. Let the pressure start at one pound and increase gradually, and then analyze the behavior of the two walls and the connecting rope. The pressure rises slowly until 296 lb. is reached, which is greater than the weaker wall can stand, and if it were not for the rope holding it up, the wall would collapse; but there is no perceptible change in conditions, as both walls still stand and the rope is still intact. When the pressure reaches 528 lb., which is the ultimate strength of the rope, the rope breaks, allowing the full load of 528 lb. to come on the weaker wall. As the latter can stand only 296 lb., both the rope and the wall must necessarily let go. It is therefore obvious that the addition of the strength of the weaker wall did not add to the strength of the rope, and the strength of the wall and rope combined was only that of the stronger member, or the strength of the rope.

Now substitute the assumed boiler for the walls and the rope. The stronger wall is equivalent to the shell of the boiler to which the pad ends of the diagonal braces are attached, the weaker wall is equivalent to the head of the boiler to be braced, and the rope is equivalent to the braces.

The boiler head is supposedly designed to burst at 824 lb. The unbraced head will burst at 296 lb., and the bracing has an ultimate value of 528 lb., and by adding the strength of the unbraced head to the strength of the braces, the result is a bursting pressure on the braced head of supposedly 824 lb. Following the same line of reasoning as was used with the stone walls and the rope, as soon as a pressure equal to the value of the braces is applied, the head will give way. That is to say, when a pressure of 296 lb. has been reached, the value of the unbraced head is gone, and when a pressure of 528 lb. has been reached, the braces give way, carrying the head with them. It therefore follows that the assumed boiler is designed to burst at 528 lb. and not 824 lb. as it was supposed to be. This is based on the strength of the braces, and dividing the bursting pressure of 528 lb. by the factor of safety of 6, it is found that the boiler is designed for a safe working pressure on the heads of 88 lb. and not 125 lb. To make the heads safe for 125 lb. working pressure, they would have to be braced for 125 lb. and the value of the unbraced head ignored.

The same argument applies to the stay-bolted furnace sheet of a vertical-tubular boiler, with a slight difference when the furnace sheet proper is stronger than the stay-bolts. In the latter case it is not permissible to figure the safe strength of the furnace and then add that of the stay-bolts and consider the sum as the desired working pressure. Assume, for instance, that the actual collapsing pressure of a cylindrical furnace is 625 lb. and that an actual collapsing pressure of 1075 lb. is desired and that stay-bolts to the value of 1075 — 625 = 450 lb. are installed to bring the actual collapsing strength of the furnace up to the desired pressure. Comparing this with the stone-wall illustration, the furnace is equivalent to the weaker wall and the stay-bolts are equivalent to the rope. When a pressure of 450 lb. is applied, there will be no perceptible change in conditions, as the walls can withstand that pressure; but when the load reaches 625 lb., the weaker wall starts to collapse, transferring the load to the rope, which is good for only 450 lb.; therefore, the wall and the rope give way. So it is obvious that the strength of the stay-bolts cannot be added to the strength of the furnace sheet and the sum considered as the strength of the stay-bolted furnace. If the example just given is reduced to safe working pressures by dividing each item by a factor of safety of, say, 6, the unstayed furnace will have a safe collapsing pressure of 104 lb. and the stay-bolts alone will be safe for 75 lb., making the stay-bolted furnace good for only 104 lb. If a safe working pressure of 200 lb. is desired, the furnace must either be strong enough in itself for 200 lb. or else the stay-bolts must be good for 200 lb. It is incorrect to add them together and call the combined value the safe working pressure.

The same argument applies to the stay-bolting of a cone top in a submerged vertical-tubular boiler and to the flat firebox sides of a locomotive-type boiler.

Summing up the entire subject, a braced or stay-bolted portion of a boiler is no stronger than its strongest part, and on no account should the strength of the braces or stay-bolts be added to the strength of the plate and their sum considered the strength of that portion of the boiler.

Some Notes on Turbine Bearings and Their Lubrication

COMPILED BY CHARLES H. BROMLEY

The data given in this article are from the author's loose-leaf notebook and have been gathered from many sources during recent years. Some engineers may desire them for their notebooks.

IT IS the consensus of opinion that the coefficient of friction slightly decreases with increasing speed. In high-speed bearings the coefficient is independent of the load.

Bearing Pressure—With slow-running bearings the pressure per square inch usually is not more than 70 to 80 lb., with white metal and forced lubrication. Bauer, Lascher & Swallow give 57 to 114 lb. per sq.in. for forced lubrication.

Temperature of the Oil—About 165 deg. F. should be considered the limit for turbine bearings, although constant temperature of 195 deg. F. may not give trouble, but the safety margin is cut down. When the oil reaches a temperature above 160 deg., it is likely that it will carbonize, therefore, 120 to 140 deg. is good practice; 250 deg. F. is the limit at which most oils have enough viscosity to be of any value in turbine lubrication.

Influence of Viscosity.—Pressure in bearings experimented on by Tower was 625 lb. due to oil being dragged in by the journal; that is, dragged in between the journal and the bearing. This teaches, of course, that the oil should be fed into the bearing at a point where the pressure is lowest.

Value of Viscosity—It is well to cite that in stern tubes of torpedo-boat destroyers, where water is the lubricant used, mean bearing pressure is limited to 20 to 25 lb. per sq.in. of projected area. Railway axles using grease go as high as 600 lb. per sq.in. of projected area.

Viscosity must be such that the oil film is carried completely around the journal without breaking down and without squeezing out of the bearing.

Stability of Oil Film—A remarkable demonstration of the stability of an oil film is shown by tests of the Westinghouse Co. (Pittsburgh) on segmental thrust blocks of a Kingsbury bearing, where with a mean surface speed of 54 ft. per sec. pressure could be (and was) increased to 10,000 lb. per sq.in. before failure occurred; but it was the white-metal facing of the bearings that flowed and not the oil film that broke down, as no serious heating of the oil took place.

Relative Position of Lubricated Surfaces—In high-speed lubrication the journal is never concentric with its bearings. This is the ideal condition, as the experiments of Osborne Reynolds and others have shown that opposing surfaces must never be parallel to each other for successful lubrication.

Specific Heat of Oil—In practice, the specific heat is usually taken as 0.31 and the specific gravity as 0.88. Battle's "Lubricating Engineers' Handbook," page 138, gives the specific heat of petroleum lubricating oil at 60 deg. as 0.4175.

The Coefficient of Friction—The coefficient of friction, or ratio of the resistance of the oil film to the load may vary, according to Stoney, from 0.0008 to 0.003, but he suggests 0.002 as suitable for usual cases where the unit pressure is about 500 lb. per sq.in.

Oil Consumption and Costs—Returns from a large number of users of Westinghouse turbines show that only about one-quarter gallon of oil is required for the bearings per kilowatt per year—"Steam Turbines," by L. G. French, p. 7. H. G. Scott in a paper read before the American Institute of Electrical Engineers, January, gave the lubrication charges per kilowatt-hour of reciprocating engines as 1.77c. and of the turbines as 0.35c. This was back in 1896, when turbines were of small capacity, comparatively.

Cooling Bearings with Water—At the plant of the Buffalo General Electric Co., Buffalo, N. Y., water is supplied from the boiler-water makeup evaporators, which are 60 ft. above the turbine floor and receive their supply from the hotwell pumps. From here the pipes are led to the turbine bearing, giving a head of 60 ft.; therefore, no extra pumps are used to handle the water which cools the turbine bearing.

Surface Speed—Land, 30 to 60 ft. per sec.; marine, 15 to 30 ft. per sec.

Ratio of Length to Diameter—Land, 2 to 3:1; marine 1:1 to 2:1.

Parsons Elastic Sleeve Bearings—For turbines with speeds of 3000 to 4000 r.p.m. Parsons uses an elastic sleeve bearing, consisting of concentric sleeves slipped endwise over the shaft. Instead of the top and bottom brasses, the concentric sleeves are used. The clearance between one sleeve and another varies from 0.002 to 0.006 in. The inner sleeve is really the bearing brass and is flanged at one end and has a ring nut at the other. The inner sleeve is thus fixed loosely in the bearing block; the other sleeves, usually two, are slipped on over the inner one, which has oil grooves and radial holes to let oil get to the other sleeve, which also has small holes in it to let the oil through. The bearing forms a hydraulic cushion which admirably stands vibration. This type of bearing should eliminate bearing trouble where chronic vibration of the machine causes a hot bearing, as may happen when severe vibration is caused by an unbalanced rotor. A similar bearing is used on Westinghouse turbines of speeds around 3600 r.p.m.

High-Speed Zoelly Machine—The high-speed Zoelly machines use a spherical bearing in which a sleeve fits over the journal, the sleeve being held in by segments resting upon spherical-headed screws.

Oil Consumption and Bearing Pressures—For high-speed bearings B. C. K. Balfrey, in a paper on "High Speed Bearings," Proceedings of the Rugby Engineering Society, Vol. 10, 1912-13, gives the practice of three English makers as:

Gal. per Sq.In. per Min.	Pressure Lb. per Sq.In.
0.05	45 to 60
0.05	5 to 10
0.01	....

Heat Loss at Turbine Bearings—The loss of heat in the bearings of well-lubricated turbines of large output is less than 1 per cent., reckoned on the total available heat.

Thrust-Bearing Clearances—Thrust bearings of the ring and collar types usually have clearance between rings and collars of from 0.002 to 0.003 inch.

Influence of Temperature on Chemical Reactions—Broadly, the higher the temperature the more rapid the chemical reaction between the constituents of the oil. At 120 deg. F., common in turbine work, chemical reactions go on, though slowly when pure mineral oil is used. The most common trouble is that caused by paraffin separating out of the oil in the form of a pasty, jelly-like substance adhering to the cooling coils of the oil cooler, greatly decreasing the rate of heat transmission through the coils. This trouble is most noticeable with oils of high viscosity, says the Westinghouse Co. An olefine-base oil avoids this trouble; but the cost is high. Russian oils are of olefine base.

Heat Transmission in Oil Coolers—The following data are from tests by M. Boella, of the Italian Corps of Naval Architects, and were given by him in an article in *Rivista Marittima*.

Explanation of types of oil coolers:

A: Cylindrical shell with two rows of U-tubes; water passing in series through tubes; oil surrounding tubes entering at bottom of shell, discharging at top; single pass, no baffles; gravity oil circulation.

B: Horizontal shell; straight tubes; water in single pass through tubes; oil surrounding tubes; three passes; counter-current.

C: Horizontal cylindrical shell; oil through helical coils, one coil inside the other (not one pipe inside another), oil inlet to inside coil returning through outside coil; water in one pass through shell.

D: Condenser type; straight horizontal tubes; oil, two passes; water, two passes; oil and water flow in same direction, that is, bottom to top.

E: Cylindrical vertical shell; short flattened tubes; oil through tubes in one pass, inlet at top, outlet at bottom; water, single pass, inlet bottom, outlet top.

Types of Oil Coolers	Weight, Lb.	Diameter, In.	Height or Length, In.	Space Taken Up, Cu.Ft.	Cooling Surface, Sq.Ft.	Weight per Sq.Ft.	Space Taken Up per Sq.Ft., Cu.Ft.	Coefficient of Transmission per Sq.Ft. per Degree Difference in Temperature B.t.u.
A	772	31.5	39.4	17.7	28.00	27.6	0.63	33 to 59
B	1,234	13.8	110.3	9.5	484.00	2.56	0.02	..
C	992	15.7	118.1	13.4	215.00	4.61	0.063	66 to 73
D	1,543	23.6	66.9	17.0	204.52	7.54	0.084	25 to 35
E	265	12.6	15.7	2.3	62.00	4.26	0.038	136 to 180

Note that the cooler E gives high heat transfer coefficient with small weight and volume.

In a paper, "Performance of Lubricating Oil Coolers," by M. C. Stuart, in the May 17 *Journal* of the American Society of Naval Engineers, some interesting results of tests were reported on three types of oil coolers, here designated A, B and C.

A: Plain tube; oil in shell in multipass arrangement; water through tubes in single pass.

B: Plain tubes, fitted with retarders; oil through the tubes in multipass arrangement; water in shell in multipass arrangement.

C: Special corrugated concentric tubes; oil between tubes in single pass; water in shell in single pass.

The coolers used were of practically the same weight and volume.

A summary of the tests follows:

Cooler	A	B	C
Heat transfer coefficient (based on unit surface) at equal capacities, B.t.u. per hr. per sq.ft. per deg. mean temperature difference	82.00	39.00	125.00
Relative heat transferred (based on unit volume) at equal capacities, B.t.u	1,000.00	450.00	450.00
Capacities, based on equal temperature drops, lb. oil per min	195.00	85.00	27.00
Oil-friction drop, based on equal capacities, lb. per sq.in. (pressure)	7.80	2.00	22.6
Weight per square foot of surface, lb	10.87	7.95	30.00
Volume per square foot of surface, cu.ft	0.49	0.53	0.15

These tests showed that the relative friction drops are in the same order as the relative heat-transfer factors and furthermore that the weights per square foot of cooling surface are in the order of the heat-transfer factors.

The summary strikingly shows that when considering the relative merits of oil coolers, all features of design should be taken into account.

Separating Water from Oil—The oil from the bearings may be heated for a considerable time to a temperature of 200 deg. F. without impairing the quality of the oil, when separating water from oil.

Testing Oil for Water—The following method is in use by some engineers of the United States Navy. Draw a small quantity of oil to be tested into an ordinary test tube; mix with the oil an equal quantity of gasoline and shake the contents of the test tube. The water will settle to the bottom. With a graduated tube the percentage of water may be determined, the quantity of oil and gasoline being known.

The Michell Thrust Bearing—The bearing surface is made up of adjustable segments, each pivoted to automatically produce a pressure oil film between the collar and bearing surface. The body of the bearing forms the oil well, and in large-sized bearings is water cooled. The coefficient of friction is about 0.0015 as against 0.03; the factor of safety at 300 lb. pressure per square inch, projected area is greater than multi-collar bearings give at 50 lb. per square inch. The friction is about one twenty-fifth that in multi-collar bearings.

The Michell Journal Bearing—This bearing for large sizes has 12 segments forming the bearing surface. Each segment is faced with white metal and rests in a spherical seat. The body of the bearing forms an oil well, the oil passing to the journal through holes, admitting oil between each segment at their seats. The following table gives the results of tests of experimental Michell journal bearing conducted by Cammell, Laird & Co., Birkenhead, England:

TEST OF EXPERIMENTAL MICHELL JOURNAL BEARING

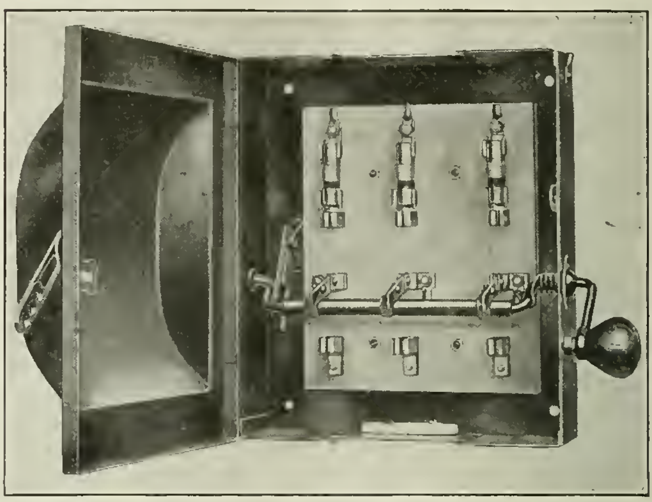
Westinghouse Thrust Bearings—The segmental thrust bearings have red-metal packing rings; the effective bearing surface is, roughly, 55 per cent. on the thrust or outer side and 45 per cent. on the inner side. The 45,000-kw. two-cylinder compound turbine at Providence, R. I., has effective bearing surface of 69 sq. in., thrust side, 54.5 sq.in., back. The maximum bearing speed at 1800 r.p.m. is 100 ft. per second.

Data on this subject are meager and widely scattered, and a really satisfactory compilation is yet to be presented.

Square D Motor-Starting Switches

The illustration shows a steel-inclosed starting switch made for three-phase motors of 5 hp. capacity or less. It was designed by the Square D Co., of Detroit, to afford protection against accidental contact with live parts, to protect the operator from being burned by the flash while operating the switch and to prevent tampering with circuits.



MOTOR-STARTING SWITCH WITH COVER OPEN

The switch is of the double-throw knife-blade type with the running side arranged for fuses. It is completely inclosed in a metal box provided with a hinged cover.

The switch is operated by a handle on the outside of the box, name-plates on the cover designating the position of the switch. Means are provided to lock the cover shut to prevent unauthorized persons from overfusing the switch or in any way tampering with the connections. A safety lock for the handle is also provided to prevent the careless closing of the switch when anyone is working on the line or the equipment controlled by the switch. Inside the cabinet a steel latch prevents throwing the switch from the off to the running position without its first being thrown into the starting position. The latch also makes necessary a quick change from starting to running position. The switch can be furnished with either straight-induction or star-delta connections. With the latter a separate main-line switch must be installed ahead of the starting switch in accordance with the regulations of the National Electrical Code.

Why Bill Reads "Power"

By Himself

The whistle had sounded, the day's work was done,
And engine and boiler had ended their run,
And fireman Bill, with the place spick and span,
Was waiting to hear from the blooming night man.
While watching and waiting, to kill a half-hour,
From out of the refuse he dug an old *Power*.

Then, seating himself in his rickety chair,
He studied the pages with painstaking care.
One article told how to pack a feed pump.
"That's rotten!" said Bill. "Gee! That fellow's a chump!"
But his brow quickly cleared, and he quit looking sour,
As he muttered, "By gum! I'll write something for *Power*."

Bill wrote out his letter—some job for a toiler—
As hard on religion as firing a boiler.
He told just how tight they should set up the glands,
And how to pack steam ends and not burn their hands.
"What's doing?" inquired his wife, with a glower.
"Oh, nothing," said Bill. "I'm just writing to *Power*."

Now, after the letter was well on its way,
Poor Bill recalled things he'd forgotten to say,
And after he'd waited in vain for reply,
Bill almost forgot it, as time scurried by.
But one night his wife, with her hands deep in flour,
Said, "Bill, there's a letter. I think it's from *Power*."

Bill tore off the end, and his hardened hands shook,
For what it contained made his wife stop and look—
Just a long yellow slip, very classy and nifty,
Telling someone to hand Bill the sum of two-fifty.
"Eureka!" yelled Bill. "That's as good as a dower,
For it gives me the chance for subscribing for *Power*."

Said Bill, "I'll invest it in reading, by heck!"
So back to New York went the long yellow check,
And when, at the end of a twelve-month or more,
Bill's wages were raised, Mrs. Bill wasn't sore.
"Good fortune," she said, "came to us in a shower
Not long after Bill started in to read *Power*."

Bill climbed some, for now he's the boss of the shift
And always on hand when the boys need a lift;
He knows when the engine is wasting her steam,
Can scrape in a bearing or calk a bad seam.
He's the friend of the men, and the Super's right bower,
But he isn't self-made—he's a man made by *Power*.

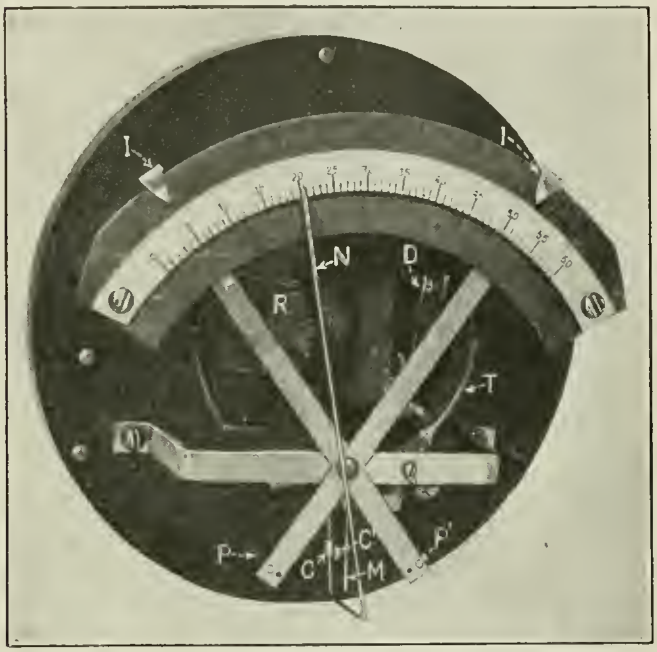
Pressure Governor for Gas and Liquid Systems

The General Electric Co. has developed a new pressure governor to control standard self-starters for motor-operated pumps and compressors for maintaining air, gases or liquids under pressure. The governor maintains a pressure between predetermined limits on any gas or liquid system that will not corrode the Bourdon tube. This governor can be used on any standard alternating- or direct-current circuit. It is rated for pressures of 80, 100, 160, 300, or 500 lb. and operates within settings of from 3 to 12 lb. between high and low pressures. Governors for higher pressures can be supplied if desired.

The governor consists of a Bourdon tube, an indicating needle, a graduated pressure scale, adjustable high- and low-pressure stops to determine the desired pressure range and a relay which actuates the contacts in the control circuit of the self-starter, all inclosed within a dustproof case, easily opened for inspection.

Action of the governor is dependent on the Bourdon tube, which should be connected to an independent discharge pipe from the pressure tank. The free end of the tube *T* in the figure is mechanically connected to the indicator needle *N*, moving it over the scale as changes of pressure affect the tube. After the settings for the pressure range have been made, the governor will automatically maintain pressure within those limits. The operation of the pressure governor is as follows:

Assuming that the pressure is at the low value, as indicated by the left-hand indicator *I*, then contact *C* on needle *N* completes the circuits through contact *C′* on movable arm *M*, which at the low-pressure point rests against stop *P′*. When this contact is made, the circuit is completed through the relay coil *R*, causing its armature to close. Attached to this armature is contact *D*, which upon closing, completes the control circuit to the self-starter, causing the motor to start. The armature is also attached to a spring which holds contact *C′* firmly against *C* until the contact is broken at *P*.



PRESSURE GOVERNOR WITH COVER REMOVED

As the pressure increases, the needle pointer moves to the right, but its lower part, to which contact *C* is attached, moves to the left and is followed by the movable arm *M*. When the high-pressure point is reached, the movable arm is prevented from traveling farther by stop *P* and the needle continues its course, breaking the circuit by separating contacts *C* and *C′*. The instant the circuit is broken, relay *R* is deënergized and its armature falls,. releasing the tension of the latter's spring, and because the movable arm *M* is counterweighted, it returns to stop post *P′*.

When the pressure has decreased to the minimum value contact *C* again completes the relay-coil circuit by engaging contact *C′* and the cycle of operation is repeated. The case is tapped and drilled at the bottom for the pressure-pipe and electrical-conduit connections.

Every dollar put into the Red Cross make not only for victory, but for everlasting peace between the great nations now fighting together in this war.

As It Is in Holland

By Y. Brouwers*

When the postman brings the paper on Saturday evening, the mistress eagerly scans it to see what is to be had from the grocer, the butcher, the milkman, etc., for we are rationed in every way. One of the most urgent questions at present is, "What shall we eat and drink and what shall we burn?" Our national mines do not supply what coal the country needs, so we depend upon importation from Germany and England. However, the Germans themselves are in want of coal because they cannot spare men enough for the mines, and this is also the case in England I suppose. Notwithstanding that, our Eastern neighbors are willing to furnish us with a limited quantity if we pay handsomely and provide the necessary facilities. So the last contract contains the conditions that we have to pay for each wagon load of about 20,000 lb. 450 guilders ($180) and have, moreover, to furnish for every wagon load a credit to Germany of a like amount. Before the war the price for the same quantity was about $40. The import from England is hampered by the want of ship capacity, and communication is dangerous on account of mines and submarines. Hence the greatest economy is necessary, for not only in the industries but also for private use coal is rationed. The industries that are most indispensable to our commonwealth, among them the factories that produce foodstuffs, receive a sufficiency. On the other hand, many factories have been forced to suspend operation of late owing to want of coal.

It is not to be wondered that many ways have been proposed and some adopted to diminish coal consumption. One of these was to limit railway traffic and not to heat the railway cars. It is only on very cold days that cars have been heated. It was proposed by an engineer in a paper at the confederation of dairy producers to replace all steam pumps in cheese and butter factories by belt-driven pumps, keeping the steam pumps in reserve, estimating that the relative steam consumption would only be about 1 to 8. He claimed that the saving would be about 6 million pounds of coal a year.

A similar case of economizing was discussed in our engineering journal *De Ingenieur* in regard to auxiliary engines on board ships. As a rule small condensing engines, consuming about 22 lb. of steam per indicated horsepower are used. One of the members of the Royal Institute of Engineers proposed to apply more economical engines; for instance, a small vertical steam engine of the uniflow type such as has been constructed by one of the professors at the Technical University at Delft, which consumes, when working condensing, only 7½ lb. of steam. Another engineer argues in a following number of *De Ingenieur* that, strange though it may seem, it is more economical to use a less economical noncondensing engine because the waste steam is used to heat the feed water and is almost always insufficient even for that purpose.

He calculates as follows, assuming that only the main engine and circulating pump engine are in operation: Assume that the circulating pump is driven by an engine using 45 lb. of steam per indicated horsepower. Steam consumption of the main engine, 3750 i.hp. × 12 lb. = 45,000 lb. per hour; circulating engine, 40 i.hp. × 45 lb. steam = 1800 lb. per hour; total boiler feed water = 46,800 lb. per hour; temperature of hotwell, 104 deg. F. Assuming that the exhaust steam from the circulating engine still contains 970.4 B.t.u. per lb. then it will give to the feed water 970.4 × 1800 = 1,746,720 ÷ 46,800 = 37.3 deg. F. rise in temperature of the total amount of the feed water. Assume that the circulating engine uses only 7½ lb. of steam, then 40 × 7.5 = 300 × 970.4 = 291,120 ÷ 45,300 = 6.4 deg. rise in the feed-water temperature. This difference must be made up from some other source, so that there is no real economy in using a highly efficient circulating-pump engine in this case. Every case should be calculated separately on its own merit.

To show the widespread interest in fuel and food conservation here, I may say that two subjects for prize competitions were published recently by some of the foremost men of our technical and commercial world, in which competitors are asked to propose methods for economy of heat force and food supply. The papers have not yet been published.

Reverse-Current Relays

A new form of reverse-current relay, Figs. 1 and 2, has been developed by the Automatic Reclosing Circuit-Breaker Co. These relays are of the circuit-opening type and are so designed that the relay will open either upon reversal of current or with zero current at abnormally low voltage. The relay is closed and held closed by a shunt-polarizing coil *P*. A high resistance is connected in series with this coil. To close the relay a push-button switch is provided which temporarily short-circuits the high resistance. The high resistance limits the current in the shunt winding to just sufficient value to hold the relay closed. A reversal of current or failure of voltage will thus cause the relay to open. These relays are designed for mounting on the rear of the circuit-breaker panel. The 1200- and 2000-amp. size, Fig. 1, has a magnetic yoke *Y*, which surrounds the upper stud of the breaker, while the 400- and 800-amp. size, Fig. 2, is provided with a series winding *W*, one terminal of which connects directly to the upper stud of the circuit-breaker. The other terminal of this winding connects to a stud *S*, through which connection to the external circuit is made.

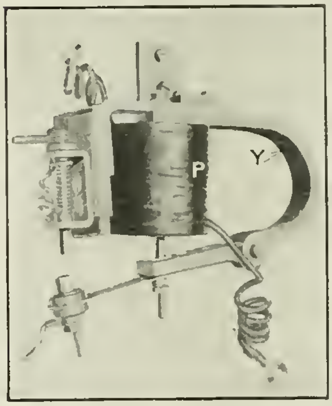

FIG. 1. RELAY, 1200 to 2000-AMP. SIZE

This Time It Is Give, Not Lend

WITHIN less than a year the American people have responded to the call of their country three different times and have oversubscribed three of the largest loans ever floated in the history of the world, each time with an increased response as evidenced by the increase in the number of subscribers from about four million to the first loan to upward of twenty million in the third. The sale of War Savings Certificates is also meeting with a hearty response and by the end of the year will show that the American people are willing to back their Government to the last dollar. But all this money is only being loaned to the Government at a good rate of interest and will be paid back in full to each holder of these securities when they mature, and our enemies might have accused us of doing this simply because it was good financial policy had it not been for what the great American Red Cross has been doing on every battle front in the world, as briefly outlined on page 700 of last week's issue of *Power*.

In fact, when we entered the war part of the German propaganda in France was to create the impression that we were a nation of money grabbers, that we never did anything except for the money we could get out of it, that the vast sums we were investing in France for great military bases, railways and disembarkation ports were not for the interest of France but to use against that country after the war to further our own selfish interests. This propaganda might have succeeded, but the call was sent forth to the people of this country less than a year ago by the American Red Cross, not for a loan at a good rate of interest, but to give outright $100,000,000 to create a War Fund with which to finance the tremendous work of relief and reconstruction that was so vital to our Allies and ourselves in Europe, and that call was answered in a way that sent a message back to Europe that the American people had donated over $100,000,000 to the Red Cross War Fund, thus giving the lie to our enemies, the enemies of right and liberty, that we are a lot of wealth worshipers.

Before this war it was looked upon as the duty of the Red Cross to take care of the wounded, but conditions have changed and now it has become their work to provide everything that human beings need in a war-devastated country. This was very clearly shown in the previously mentioned report and is further emphasized by the following paragraphs taken from a Red Cross leaflet, "What Does the Red Cross Do?" by William Allen White, a copy of which can be secured by applying to any Red Cross Chapter:

"Over in France where French soldiers are coming back from the trenches on furlough, canteens have been erected by the Red Cross in order that the men might have lodging, food and bath, and a clean resting place. Such men return home clean and happy instead of wet and hungry. They come back from their homes to the trenches to fight, not in a sullen but in a happier frame of mind because of this Red Cross work. In France, too, the Red Cross supplies fuel and food and shelter to the soldier's families so that the men are prepared to stick—stick—and stick to the end, full of courage and ginger.

"Less than a week after the Italian breakdown the American Red Cross was in Italy with long lines of freight cars loaded with surgical supplies, food and clothing for civilians and distributing this aid to the hospitals and to the hundreds of thousands of refugees, men women and children, fleeing from the German invaders and making America felt for brotherhood in Northern Italy as no other country was ever able to make itself felt in the world before."

Since the first call the demands upon the Red Cross War Fund have been tremendous, the work accomplished staggers the imagination, but the first fund is nearing exhaustion, therefore the American people have again been asked to give $100,000,000 more, during the week May 20-27, to create a second War Fund so that the magnificent work that has been started may be continued. Let the answer to this appeal go echoing back to Europe from one hundred million loyal Americans that they have again cheerfully given over $100,000,000, to create a Second War Fund.

Give to your Red Cross until your heart says stop; it is "A great net of mercy drawn through an ocean of unspeakable pain."

Tube Failure in Water-Tube Boilers

TIME and experience have pretty well demonstrated that liability to complete disruption, with the destruction of property and loss of life that attends an old-fashioned boiler explosion, is much reduced in the water-tube boiler. The casualty statistics, however, show this type to be quite liable to local injury by rupture of the tubes, the bursting of a water tube being a much more frequent mishap than the collapse or failure otherwise of a fire tube. While most cases of bursting of water tubes undoubtedly result from overheating on account of oil or sediment preventing proper water contact, still there have been many such accidents that were apparently due to a breakdown of the strength and durability of the material under the stresses of long service. The latter cause may be wrongly ascribed for a tube failure on the strength of an absence of foreign matter from the surface of the tube, as revealed by an inspection following the explosion. The fact that no incrustation is found inside an exploded water tube is no indication that the rupture was not due to overheating. The shock at the instant of the explosion is pretty certain to jar the deposits loose, allowing the current of water and steam rushing at high velocity toward the opening to thoroughly wash them out.

When a tube failure results from overheating, the rupture is preceded by a softening and bulging of the overheated area and a consequent distention of the metal, so that when it finally rips open, the edges of the fissure are drawn down to a knife-edge. Of course a thin edge along the rip might also indicate a wasting away of the material by corrosion and abrasion; but if such be the case there will be corroborative signs that will be absent if the injury has resulted simply from overheating. One of these signs is that if the tube is measured roundabout from edge to edge of the rupture, the distance will be found to equal the normal circumference of the tube. If the failure has resulted from overheating, the preliminary stretching to which the metal was subjected will be shown by the measurement roundabout at the place of rupture being greater than the normal circumference.

A particularly insidious cause of injury to water tubes is the oil that gets into the boilers in plants where proper means are not used to separate the oil from the exhaust steam that goes to heat the feed water. A very small quantity of oil thus misplaced can do an immense amount of damage. It may also prove very elusive. It may spread out on the metal surface in a film so tenuous, or may combine so unobtrusively with the solid impurities to form sludgy deposits, as to escape even the practical eye and touch of the inspector. Overheating on account of oil usually extends over a larger area, and the resulting rupture is more violent in its effects than where the destructive agent comprises simply the ordinary scale-making ingredients, and these indications furnish the only guide in assigning the true cause of failure in many cases.

Scrupulous care should be exercised to keep oil out of steam boilers. Very often those responsible appear to be lacking in appreciation of the injury it can do, if one is to judge by the indifference manifested toward the oily scum that is to be seen on top of the water in many gage-glasses. When a grease line shows in the water glass, it is high time to do some industrious figuring on the problem of purifying the exhaust steam before it mingles with the feed water. Oil-extracting apparatus is to be had, which, if intelligently installed and cared for, will eliminate danger from this source.

But the tubes of a water-tube boiler may be free from scale and oily deposits, and still burning and bagging will develop by reason of the extremely hot fires commonly carried in large power stations. The bottom rows of tubes invariably suffer in such service, notwithstanding extreme vigilance to keep them clean. It is possible that the water coursing through these tubes is heated so rapidly that it cannot pass out quickly enough to carry away the globules of steam as fast as generated, with the result that they gather momentarily in pockets next the surface of the tube, thus excluding the water from contact with the metal. It is presumed, of course, that the accumulation of steam bubbles is of very short duration; but with the fierce heat of the furnace impinging directly upon the tubes with the concentrated intensity of a blow-torch, it requires but little time to soften the thin area of exposed metal to the bulging point, and a bag is the immediate result. Often a tube is found bagged along the sides. This seems to substantiate the theory of burning on account of steam pockets, since the natural precipitation of foreign particles in the water would evidently result in bags due to this source appearing along the bottom of the tube.

A variety of causes may contribute to the deterioration of water tubes. Of these the corrosive action of acids in the feed water internally and of sulphurous compounds externally are perhaps the most common. The fine fly ash that collects around the ends of the tubes and works in beneath the baffle tiles is also a prevalent source of decay. Removal of these deposits is an item that is generally neglected when the boiler is gone over at cleaning time. Great care will be observed to keep the insides of the tubes clear of corrosive agents, but little attention will be given to the outside. With some makers of water-tube boilers the water that is splashed around while washing out works in between the headers and through hollow stay-bolts, thus saturating the deposits of fine ash and initiating a rapid process of corrosion, perhaps utterly spoiling some of the tubes if the boiler stands idle for a considerable space of time. Instances have also been reported of baffled tubes having been worn dangerously thin by rubbing on the tiles due to the constant changing of form in the boiler.

Sometimes a water tube lets go on account of an imperfect weld. In such cases there can be no room for conjecture, the evidence of deficiency in a broken weld being so plain that the cause of the failure is never in doubt. There can be no absolute certainty about the security of a weld. Despite the utmost precaution in the manufacture of lap-welded tubes and rigid inspection of the product as it comes from the mill, defects in the welding will now and then crop out. Instances of imperfectly welded tubes continuing in service for months before bursting open have been reported.

The fluctuation of pressure and temperature in the ordinary working of a boiler, by producing a succession of molecular stresses that tend to crystallize the material, is also an active cause of deterioration, although its effects are never manifest to ordinary inspection. Loss of tenacity and ductility, and of the essential property of resilience or springiness is the inevitable penalty of age in a steam boiler. In water-tube boilers the tubes have practically the whole burden of service, since they comprise almost the entire heating surface of the structure; they fulfill, in fact, so far as absorption of heat is concerned, the same purpose as the more substantial furnace sheets of fire-tube boilers. The tubes should therefore be the objects of critical inspection. As the boiler ages, even though the tubes be kept free from oil and scale and show no visible signs of decay, it might still be the part of prudence to cut one out once in a while so as to determine by test just what the condition of the material may be.

The most unfortunate thing about a water-tube explosion is that it generally means death or painful injury by scalding to the fireman or stoker attendant, and perhaps to others who may be near-by; the damage to the boiler and setting in most cases is small and easily repaired. The menace to human life that is involved is certainly the outstanding reason why every precautionary measure available should be applied to minimize these accidents.

The most hopeful item of news bearing on the possibility of a coal shortage next winter is the announcement of an order by the Government, with deliveries promised through the summer, of 1025 locomotives and 100,000 freight cars.

Correspondence

A Talk to Firemen on Saving Coal

I read with interest the lecture by Mr. Bromley at the Baltimore City Club, as published in *Power* some time ago (Jan. 22 issue). The American Society of Mechanical Engineers deserves praise for bringing about such a meeting. More should be done in that direction.

"Employers Need Education" reads a subhead in the article. This is true, indeed. As every engineer knows, when he asks his employer for a new device, one that invariably is sure to save coal, he is usually told to wait, that labor and material are too high at present. The engineer usually concludes then something like this: "Very well, Mr. Employer, if you do not want to listen to me, you can go on wasting coal. I do not have to pay for it directly." But this attitude is as disagreeable to the engineer as to anyone else.

Here are some suggestions on coal saving that engineers may find applicable without the use of new apparatus.

When a plant of any size is started in the morning, generally engines, pumps, etc., are started some time before the working day begins; that is, before the load comes on. The engineer should have the machines warm, but start them as near the beginning of the working day as conditions permit. Do not have machinery running before it is needed. At noon be ready to shut down as soon as the whistle blows. In the evening perhaps some of the engines or other machines may be shut down before quitting time. Do not wait until you shut down all the other machines just to save a trip. Send the oiler or helper to do it if you are too busy. The heads of the different departments should coöperate with the engineer and notify him immediately when they can spare an engine; also they should not allow their men to waste steam.

The engineer should keep in close and constant touch with his fireman, should let him know when the heavy load is about to come on or be taken off. If the fireman is treated that way, he will no doubt like his engineer and take more interest in the work. During the time the plant is in full operation, the fireman should not be called to do work other than caring for the fires and the boilers. WILLIAM L. KEIL.

Philadelphia, Penn.

Setting the Clock Back Again

The editorial in the issue of Apr. 9 on daylight saving seems timely, and I hope the solution will put all sections of the country on a more equal basis with reference to the sun. The Central and Mountain Standard zones are too wide at present to give all parts of the zones an equal chance to get the most benefit from the available daylight. To illustrate, consider two strips of territory—the eastern and the western fourths of the Central zone. The recent change of the clock puts the western strip one and one-half hours ahead of the sun, which is excessive, as it will necessitate the use of light in the mornings till well toward summer and for a period in summer it will be bedtime by the clock while yet daylight, both of which factors tend to defeat the purpose of the law; while the eastern strip is merely advanced to the position formerly held by the western, and as far as daylight saving is concerned, the eastern strip is doing no different under war conditions than has normally been done in the western strip ever since standard time was adopted.

Another feature is this: Under the old way the daylight comes so close to 6 p.m. in the western strip that the peak before 6 p.m. is negligible, while in the eastern strip, which is one of the greatest coal-consuming sections of the country, they have had the extra burden of an enormous peak load for some time before 6 p.m. every day. I have often wondered why more of the cities in that section have not adopted local time to do away with the burden, but the reason probably is that habit has such a hold on men.

As to keeping the clock as at present the year round, it would put the eastern strips of the Central and Mountain zones in the positions formerly held by the western strips, or local time would be about half an hour ahead of the sun, which I consider almost the ideal. Perhaps 45 minutes ahead of the sun would be a little better as it puts the sun on the meridian almost exactly midway of the working day. It would do away with the greater part of the peak load before 6 p.m. in winter and in summer would give all the extra daylight needed. It would produce an increase of load in the morning, but not nearly as much as to offset the gain caused by the drop of the early evening load. If it is decreed that the clock shall not be put back, I hope that the Central and Mountain zones will be split into several, for unless that is done the inhabitants of this strip will be groping in the dark "of mornings" for three-fourths of the year.

Exeter, Neb. W. M. ALEXANDER.

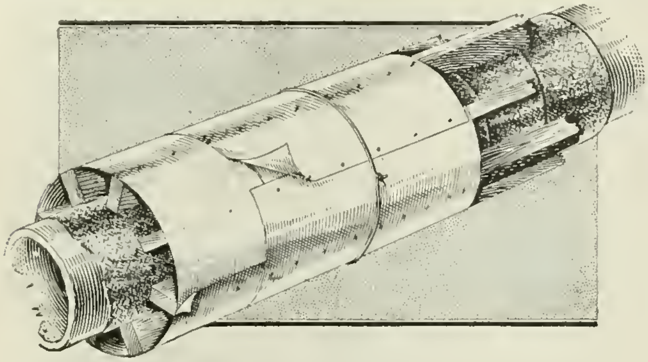
Burning Slack Containing Excessive Moisture

In my article in the issue of Apr. 2 on "Burning Slack Containing Excessive Moisture," an error in the printed figures has been brought to my notice, the stoker speed in our test being stated as averaging 2 ft. per min. This is obviously a mistake, and I find my original copy reads "No. 2 Stoker Speed," which is the record of the indicator connected to the stoker grate. In case this should not be clear, I recently checked the actual speed of this grate at the speed given, and find it moves 1 ft. in 5 min. The grate frontage is 7 ft., and the thickness of the fire 4 inches.

Calgary, Alta., Canada. JAMES F. MCCALL.

Easily Made Pipe Covering

The illustration shows how a fairly good pipe covering can be easily made. To lengths of building or tarred paper three or four feet long (the usual width of the roll) nail strips of wood equally spaced and about three inches short of the edges of the paper, as shown. This completes the outside of the covering. Wrap asbestos paper around the pipe to be covered and tie it on with stout twine, then put on the strips of wood and tarred paper and tie them on with a few turns of wire. This makes a fairly good insulator at a low cost. Care should be taken to see that the outside paper joints overlap at the sides and ends and that there are no holes, as the efficiency of the insulation depends to a large extent on the dead-air space. Painting the covering over occasionally with hot pitch will improve its quality and life.



COVERING APPLIED TO PIPE

How Pat Saved a Barge by Sinking It

His name was Pat and his hair was as red as his wit was spontaneous. He was a shoveler on a coal barge on one of the steel company's routes up the Allegheny. The particular coal barge on which Pat was stationed was "docked" for the winter above the Sharpsburg bridge, and it was Pat's duty (and his pleasure be it said) to board the barge every morning and see if it was dry and, if not, to pump it out.

Pat was fulfilling his responsible duties one day while a carpenter was busy at work repairing the footboards of the barge, and all the while the water was rising in the river at the rate of about a foot every two hours. About noontime Pat said to the carpenter: "It is meself that's thinkin' that the wather is low enough to rise higher and if the ice comes down from up beyant, this old boat will be our coffin, begum."

The carpenter, looking upstream, saw a white streak coming around the point at Aspinwall and shouted to Pat to pull the barge to shore, knowing from experience that this white streak meant ice and that ice with a current meant—well, not death, but as near to it as he wanted to be. Pat tugged on the lines forward and the carpenter pulled on the lines astern, but with the current in the river about six miles per hour, the ice came down on the barge, tearing it from its moorings with Pat and the carpenter still on duty at their respective posts.

As Pat was forward at first and the carpenter astern downstream, Pat thought it his duty to be subordinate to his superior; but as the ice took the barge with Pat at the stern, as it were, he became captain and forthwith commanded the other to keep a sharp lookout for a jumping-off place. When they neared the P. R.R. bridge, the lookout yelled: "Pat, we are done; the water is so high that we can't go under the bridge, and the two of us and the barge will go to hell in ten minutes."

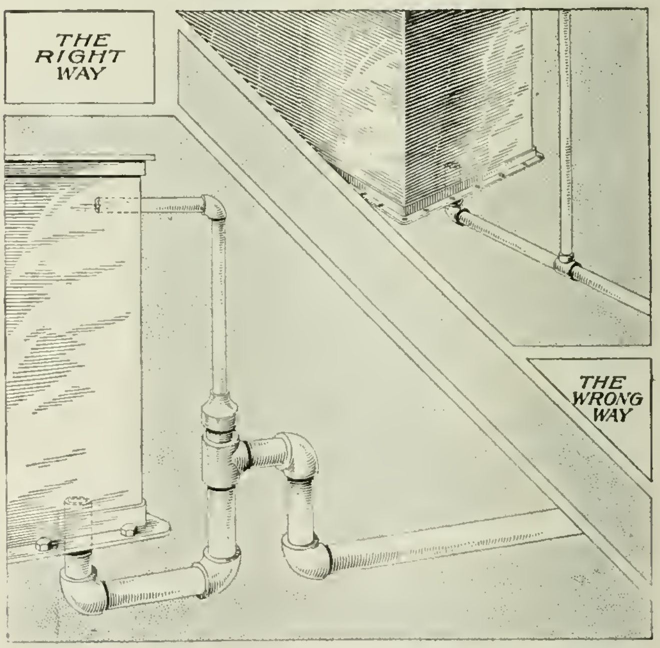
Pat, the captain, yelled: "Take your domn auger and bore some holes in her bottom to let the water in and get her low enough to go under the bridge; then plug the holes." It was done, with the result that Captain Pat and the carpenter were taken off the barge at East Liverpool and the barge was salvaged at Newport, Kentucky.

G. E. MICHAEL.

Pittsburgh, Penn.

Keeping Oil Out of Feed Pump

The same principle involved in the piping arrangement shown by T. A. Marshall in the issue of Apr. 30, page 630, that makes it impossible to entirely empty a receiving tank or heater by accident and get the oil and scum that is always found floating on the top of the water into the feed pump and boilers, may also be applied, as shown in the illustration, to open heaters, etc., in which there are trays and the like in the way of internal piping. The pump suction from the heater should be arranged somewhat as shown to form a seal, and a small vapor pipe connected from the tee at the top of the seal to the steam space of the heater or tank. The action is, of course, the same as that described by Mr. Marshall. It is not safe to allow the vapor pipe to be simply open to the atmosphere in case of a closed tank, because, in the event of even a slight pressure in the heater, all the water may be discharged from it before the pump gets air or vapor. Connecting a vapor pipe into the side of a tee, as I have seen tried, won't do either, for obvious reasons.



OUTSIDE PIPING TO KEEP SURFACE OIL FROM PUMP

New York City. J. LEWIS.

Fitting a New Piston Valve

My experience in putting a new piston valve in a Buckeye engine may be of value to some brother engineer, so I give it for what it is worth.

After pulling in the new valve-chest bushing, which necessitated the removal of the crank-end valve-chest head and stuffing-box, my assistant replaced the head, and upon attempting to insert the new valve I found it rather a snug fit; in fact, it would go only about halfway in. I discovered that the valve rod was binding on the top where it passed through the stuffing-box. The shoulder on the chest head, intended to fit the counterbore of the chest, was about one-eighth inch smaller than the bore, which allowed the head to drop down out of line; the slack of the studs in the holes also allow this. Loosening the stud nuts and raising the chest head slightly so the stuffing-box would be central with the valve-chest bore corrected the difficulty, and the valve entered properly. W. D. WAKEMAN.

Deposit, N. Y.

Single-Phase Motor Would Not Carry Its Load

Some time ago I had occasion to investigate trouble in a single-phase motor of the split-phase, clutch type that would not carry its load. It would start and increase in speed until the clutch began to grip, and at this speed it would remain until all the load was taken off, when it would come up to full speed. If the load was put on again, it would slow down until the clutch slipped. Considerable work was done on the clutch as the electrician thought the trouble was in this part of the equipment. However, when I investigated the matter, I found many of the rotor bars loose, and upon resoldering these, the motor ran as satisfactorily as when new. The reason for the motor slowing down is as follows:

The action in a single-phase motor is somewhat different from that of a polyphase machine. In the latter the revolving magnetic field is independent of the rotor's speed. A resistance in the rotor circuit will have the effect of changing the speed at which the maximum torque will take place, the maximum torque being of practically the same value regardless of whether it occurs at standstill or near full speed.

In the case of the single-phase motor the revolving field is dependent on the rotor's speed, being maximum at full speed and becoming simply a pulsating field as the rotor comes to rest. In this type a rotor resistance not only has the effect of reducing the speed at which the maximum torque will be developed, as in a polyphase machine, but also it reduces the amount of torque until at standstill the torque becomes zero.

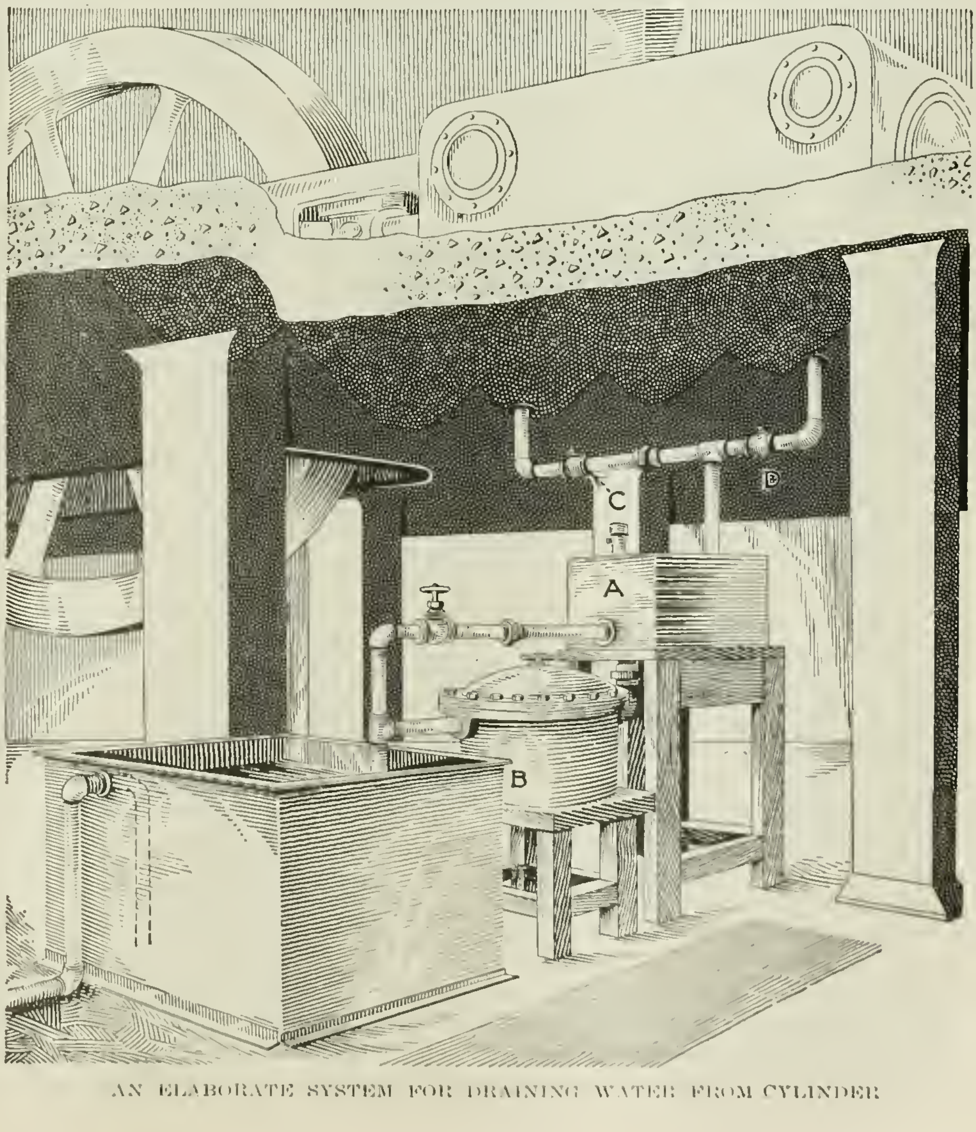
Adams, Mass. ALBERT CARPENTER.

Cylinder-Draining System

The illustration shows a rather elaborate cylinder-draining outfit that may be interesting. The globe valves on the drain lines above the floor are not shown; *C* and *D* are check valves, *A* is a cast-iron receiver and *B* is a trap.

Considerable water came over with the steam at times, but by leaving the draining valves above the floor open, the water got away all right. It was found that the cylinder oil soon closed up the trap discharge, so the outlet was drilled out to about twice its former diameter, and it did not choke up any more. The trap discharged into an open tank with a discharge overflow as shown, and most of the oil was skimmed from the top of the water in the tank and after being passed through a filter was used for oiling shafting, etc.

Portsmouth, Ont., Canada. JAMES E. NOBLE.



AN ELABORATE SYSTEM FOR DRAINING WATER FROM CYLINDER

Burning Slack Containing Excessive Moisture

The stoker setting described in J. F. McCall's article in the issue of Apr. 2, page 472, is by no means new, being generally similar to a standard Babcock & Wilcox Limited chain-grate stoker setting for low-volatile coals, which has been used for many years in England and Europe. In 1913 one of these B. & W. stokers was installed at the University of Alberta, Edmonton, which has proved very satisfactory in burning the Edmonton lignites, and a series of tests were being carried out by C. Robb, professor of mechanical engineering, when the war broke out and the work was held up. Some changes in the settings of the chain-grate stokers along the same lines have been made at the city power plants of Edmonton and Saskatoon by their city engineers.

While Mr. McCall's setting includes the essential center arch with an opening behind it, which is the best arrangement possible without more extensive changes to the standard bituminous-coal setting, still better results would probably be obtained by the regular B. & W. setting in which the back arch is set at a slope to obtain the maximum reflecting power, the grate inclined and a larger combustion space obtained by increasing the furnace height. The horizontal front arch is of little value, and as sub-bituminous and lignite coals do not take long to burn out, the length of the grate need not as a rule be over ten feet, the front of the stoker being set closer into the front of the boiler. This type of setting will prove satisfactory when burning the better grades of lignite. For lignites containing a high percentage of moisture, a special extension is employed at the front of the grate for partially drying the fuel before passing on to the chain grate proper.

In view of its present importance the question of the most satisfactory way to burn the Canadian lignites is engaging the general attention of engineers, and the Canadian government recently passed a special grant for an experimental plant in Saskatchewan. While some valuable investigations have been carried out by the United States Bureau of Mines, it would be of additional interest to hear from others who have had experience in burning lignite containing over 25 per cent. moisture under boilers. F. A. COMBE.

Montreal, Que., Canada.

Combustion in Boiler Breechings

I read with interest the experiences of Mr. Sonntag in regard to the gas burning in the breeching of boilers equipped with forced-draft apparatus, in the issue of Mar. 26, page 448, and having had experience with high-volatile coals and various kinds of furnaces, I think possibly the following may be of interest. I feel sure that Mr. Sonntag's conclusions are correct—that the gas burning in the breeching is the result of insufficient oxygen to support combustion, which causes the flame to reach out for more. A kerosene lamp will demonstrate this condition, as any slight reduction of air through the burner will cause the flame to lengthen.

It is generally recognized that successful forced-draft installation depends on a restricted and uniform air supply to the fire. Eliminating excess air is vital to good efficiency, so that the foregoing condition warrants a lot of consideration, as there is a possibility that the condition that did exist in this case could be made to produce remarkably good results if a few minor changes and experiments had been made. For such a condition I would suggest a few encircling tile directly over the bridge-walls to give the gas an incandescent surface to impinge on, creating a zone of much higher temperature than can be obtained otherwise, and then by firing alternate doors there is a chance for the fire to get sufficient free oxygen well mixed and ignited at this point, so that the gases will be consumed in the combustion chamber instead of in the breeching. A still better method is to construct arches of short spans, approximately four feet wide, over the bridge-walls, which, on account of being narrower than the boiler, will make a much better mixing medium.

I have records of tests on Heine boilers with properly arranged forced-draft grates and furnaces, using Southern Kansas coal of a very rich volatile content, where the temperature in the combustion chamber reached over 2000 deg. F. when carrying heavy loads, and the stack temperatures reached but a fraction over 600 deg., with the waste gases showing only a trace of carbon monoxide. I have also made exhaustive experiments at a reduction works in Colorado City, where Colorado lignite coal is burned with a forced-draft furnace especially designed for that fuel, in which preheated air is introduced between the furnace and the combustion chamber; and by controlling this air, the length of the flame on the hearth can be changed from 20 ft. to as high as 70 ft. The flame can be controlled in the same way under the boilers, which are similarly equipped in this plant. Forced draft is getting to be the favorite method of burning slack and high-volatile coals on account of the high boiler efficiencies maintained. My experience has taught me that it is much easier to add a little air at the proper place in a furnace under slight pressure than to fight the eternal excess that filters through boiler settings and fuel beds in poor condition caused by poorly designed grates. WILLIAM J. MANHIRE.

Kansas City, Mo.

Volumetric Efficiency of Air Compressors

The apparent volumetric efficiency of an air compressor is the apparent volume of free air drawn in divided by the piston displacement; the cylinder clearance is, of course, considered in the calculation or determination. This efficiency is usually about 96 to 97 per cent. with modern valves.

Paradoxical as it may seem there is a two-stage steam-driven air compressor at Newport, R. I., that shows a volumetric efficiency of 116.8 per cent. as shown in the records of tests on file in Washington. You don't believe it? Neither did I when it was first brought to my notice, but I believe it now. Here is the reason: The cold-air inlet is a long pipe extending to the river bank, and when suction starts in the compressor it sets in motion the long column of air in the inlet pipe, the momentum of which partly compresses the air in the low-pressure cylinder before the inlet valves are completely closed. Do you believe it now?

Pittsburgh, Penn. G. E. MICHAEL.

Inquiries of General Interest

Effect of Superheating on Valve Leakage—What effect has the use of superheated steam on the leakage of engine valves? W. R.

In all forms of valves the tendency to leakage is increased, as the higher temperature of the steam causes greater distortion of the parts and at the same time the steam is less dense.

Quick Rise of Compression Line of Indicator Diagram—What causes the quick rise in the compression line frequently observed in steam-engine indicator diagrams? W. R. S.

A quick rise of the compression line may be due to the compression steam taking up heat from the cylinder and also may be due to the addition of steam that has leaked past the inlet valve.

Expansion Tank for Hot-Water Heating—What size of expansion tank would be suitable for a hot-water heating system having about 750 sq.ft. of radiation? S. F.

Expansion tanks for hot-water systems containing 500 to 1000 sq.ft. of radiation should have a capacity of about 1 gal. per 40 ft. of radiation. For 750 ft. of radiation a tank of 20 to 25 gal. capacity would be sufficient.

Ratio of Expansion—What is meant by ratio of expansion in a simple engine and in a compound engine? J. L.

The ratio of expansion of the steam used in a simple engine is the quotient derived by dividing the final volume of steam found in the cylinder by the initial volume. By initial volume is meant the volume of steam admitted to the cylinder up to the point of cutoff plus the clearance volume, and by final volume is meant the volume of the cylinder, plus the clearance volume. In a compound, triple or any other form of stage-expansion engine, just as in a simple engine, the total ratio of expansion is the ratio of the final volume of steam found in the last cylinder to the initial volume in the first cylinder.

Dry Pipe Preferable to Steam Dome—Why is a dry pipe for a horizontal return-tubular boiler preferable to a steam dome? S. P.

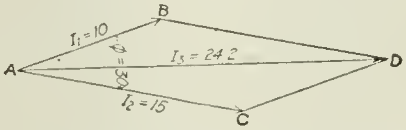
A steam dome takes up headroom, affords a large surface for loss of heat and the construction impairs the safety of the shell. The strength of the riveting and staying of a dome to the shell is uncertain, as it depends on the holding power of rivet heads, and the unequal expansion of the dome flanging and boiler shell is likely to cause leakage that cannot be stopped by calking. None of these disadvantages is present from use of a dry pipe, and when it is properly designed and placed within a boiler, mechanical separation of water that is entrained in the steam may be obtained as effectually as by use of a dome of ordinary dimensions.

Changing Direct-Current Motor's Voltage—What changes are necessary to be made in the windings of a 4-pole 240 volt compound-wound motor, running 1350 r.p.m., to operate on 115 volts and run at one-half its original speed, or 675 r.p.m.? T. A. M.

The only changes necessary are in the shunt-field windings. The shunt-field coils must be arranged in two groups of two coils in series in each and the two groups connected in parallel. To obtain the same amount of compounding as when the machine was operating on 240 volts it will not be necessary to make any change in the series-field windings. The machine will take the same current at full load on 115 volts as it did on 240 volts and develops one-half the number of horsepower. On account of 115 volts being slightly less than one-half of 240, or 120 volts, the speed on the new connection will be slightly less than one-half that on the higher voltage. The ventilation will not be quite so good on the lower speed, therefore the full-load temperature may be somewhat higher at the low speed.

Value of Two Alternating Currents—An alternating current of 10 amperes is out of phase by 30 deg. with a second current of 15 amperes. What is the resultant value of the two currents? H. F. S.

The resultant of two or more alternating currents in a circuit is always equal to their vectorial sum. The angle between the two currents in this case is 30 deg., hence the angle ϕ, between AB and AC representing the two currents in the figure, is made 30 deg., and by completing the parallelogram the resultant AD is obtained, which represents to scale what an ammeter would read when the two currents were flowing through it. This resultant may be calculated by the formula,



$$I_3 = \sqrt{I_1^2 + I_2^2 + 2I_1I_2 \cos\phi}$$
$$= \sqrt{10^2 + 15^2 + (2 \times 10 \times 15 \times 0.866)} = 24.2 \textit{ amperes}$$

Determining Advantage of Speeding Up Engine—How is it determined whether there would be an advantage from speeding up a Corliss engine with the present load? W. V. B.

As the advantage would depend on the superior economy from shorter cutoff combined with increased piston speed, the first step would be to determine the mean effective pressure necessary and from that to determine the new point of cutoff and the relative steam economy at the proposed speed. For the same load, the m.e.p. to be realized with different speeds is inversely as the speeds, and the required m.e.p. would be found by multiplying the present m.e.p. by the present speed and dividing the product by the proposed speed. Adding the m.e.p. to the average absolute back pressure gives the average absolute forward pressure and this divided by the absolute initial pressure will be the average forward pressure to be realized per pound of the initial.

Inspection of a table of mean pressure per pound of initial with different clearances and points of cutoff (such as given on page 115 of Low's "Steam Engine Indicator") will show the point of cutoff required. The relative amount of steam admitted with the present point of cutoff and number of strokes per minute can be compared with that required by the new point of cutoff and proposed number of strokes per minute. Such a comparison can only be approximate, however, as in the different cases there is likely to be different variation of the actual from the theoretical diagrams made by the engine. A closer estimate of relative economy could be made from comparison of actual diagrams obtained with the present speed for the average load and with the engine loaded only sufficiently for obtaining the m.e.p. that will be required by the proposed speed. If the proposed increase of speed is within limits of safety and certainty of operation of the engine, feed-water tests of economy of steam required per horsepower per hour for the present average m.e.p. and for a load that requires approximately the proposed m.e.p. at the present speed would give results near enough for all practical purposes to be regarded as identical with relative results of tests made at the actual speeds.

[Correspondents sending in inquiries should sign their communications with full names and post office addresses. This is necessary to guarantee the good faith of the communications and for the inquiries to receive attention.—Editor.]

Washington & Idaho Water Power Co. Valuation

In the hearings being conducted by the public-service commissions of Washington and Idaho at Spokane relative to the value of the Washington & Idaho Water Power Co., R. H. Thomson, former city engineer of Seattle, gave the properties a substantial boost in value.

Called as an expert on power-site values, he has given two months since the adjournment of the hearing in February to a study of the company's power sites, water-storage system, power plants and their relative costs as compared with other plants similarly situated. The total value of the company's properties is given as $26,000,000.

Engineer Thomson found that the power development of the Washington Water Power Co. was installed at a much less cost than that usually estimated, and for that reason he placed a valuation on the company's power plants, overflow rights and impounding systems of approximately $5,000,000 more than its book costs show. He called this the "value of opportunity," which he held entitled the company to a valuation which it would expect to ask were it about to sell its property to an outside purchaser. Should the joint commission accept the views of Thomson, it will mean an addition of 20 per cent. to the value of the company's property as given in former testimony and will entitle the company to increase its rates.

The Washington Water Power valuation hearing is being held preliminary to rate making by the public-service commissions of Washington and Idaho. The appraisal by the engineers of the Washington and Idaho commissions has been in progress more than three years. The greater part of the testimony of the engineers for the two states was taken in February, at which time R. H. Thomson was retained for a further inquiry as to power-site values by the Washington commission, and the City of Spokane retained Otto A. Weille, former city engineer, for testimony in behalf of the city. J. C. Ralston, former city engineer, appeared as an additional expert for the Washington Water Power Co., making three engineers representing the company, the others being Carl F. Uhden, chief engineer for the company, and Henry L. Gray. J. B. Ingersoll, former chief electrical engineer for the Inland Empire system, attended the hearings in consultation with counsel for the city.

For the Washington commission are appearing E. F. Blaine, chairman; F. I. Spinning, and Harry Lewis. The members of the Idaho commission in attendance are John W. Graham, chairman; George E. Erb and L. A. Freehafer. Hans Cleland, assistant attorney general, appears as counsel for the state, and J. P. Pope, assistant attorney general of Idaho, is counsel for the commission of that state. Frank T. Post is counsel for the Washington Water Power Co., and Mayor C. M. Fassett, J. M. Geraghty, corporation counsel, and A. M. Winston, assistant corporation counsel, appear for the city. D. F. McCurrach, acting chief engineer, and J. S. Simpson, former chief accountant, appear as technical experts for the Washington Commission. W. G. Swensden, chief engineer for the Idaho commission, is in attendance.

R. H. Thomson, the first witness called, said that power sites installed under similar conditions as those that obtained with the Washington Water Power Co. cost $225 per hp. The great Montana plants, the closest competitors of the Washington Water Power Co., he said, cost $215 per hp. He was surprised at the comparatively low cost of horsepower development shown in the invoice costs of the Washington Water Power Co., which is lower than the average costs over the country. He said that this difference is due to the advantageous location of the company's four plants on the Spokane River, with common impounding of water-storage facilities in Cœur d'Alene Lake. The company appears to have exercised prudence and close supervision in the building of its plants, as disclosed by its book costs. He claimed that the company in determining the value of its property is entitled to the difference in what its development has cost per horsepower as compared with what similar developments have cost elsewhere. Allowing ordinary conditions of growth and a favorable field in so far as competition is concerned, he would place this value of opportunity at $4,931,251.

Engineer Thomson produced the cost of power development per horsepower for the plants of the Washington Water Power Co., together with the credit due each plant compared with the going costs of such development for other companies:

Plant	Cost per Hp.	Hp. Development	Credit Due
Post Falls....	$168	5,930	$278,710
*Spokane..........	151	26,700	1,708,000
Long Lake Plant........	147	42,918	2,918,220
Little Falls Plant..............	120	18,130	1,722,350

* Estimated on basis of proposed new $3,000,000 plant.

He stated that this makes a total excess value of $6,628,080 over and above what might be styled invoice value of water rights and sites, including lands for impounding purposes, belonging to the Washington Water Power Co. This sum plus the invoice value will be at par at such time as the market demands of the territory will consume the normal output of the plant. Figuring on the basis of ten years being required for the territory to absorb the full output of the company, $4,931,251 would be a conservative figure as to the excess value.

Engineer McCurrach, for the Washington Commission, presented a supplemental report, bringing the appraisal of the Washington Water Power Co., to December, 1916, as compared to June 30, 1915, the date covered in his first report. This subsequent appraisal is based on additions actually made to the properties since June 30, 1915, as shown by the books of the company. Prices are based on the five-year average from 1910 to 1915. Following are the figures:

WASHINGTON PROPERTIES

	June 30, 1915	December, 1916
Railway system.................	$5,502,422 00	$5,593,214 00
Light and power system..............	13,505,694 00	13,834,977 00
Nonoperating property................	893,855.00	893,785.00
Totals.........................	$19,901,971.00	$20,321,976.00
Land railway....................	447,004.00	438,453 00
Land-light and power.................	1,114,904 00	1,114,232.00
Totals.........................	$1,561,908.00	$1,552,685.00

IDAHO PROPERTIES

Light and power systems...............	$2,326,669 00	$2,478,890.00
Nonoperating property...............	42,586.00	42,586.00
Totals....................	$2,369,255.00	$2,521,476 00
Land-light and power...............	123,560.00	143,203.00
Grand totals Washington and Idaho...	$23,956,694 00	$24,519,340 00

Another table of appraised values was presented by Engineer McCurrach, prepared at the request of F. P. Post, attorney for the power company, based on prices prevailing from 1912 to 1916, a period in which materials and labor cost more. These figures showed:

Washington totals	$23,490,484 00
Idaho totals.......................	2,839,626.00
Grand total	$26,330,110.00
Increase over regular appraisal figures.......	1,810,770 00

The appraisal of Engineer McCurrach on the railway property of the company to December, 1916, on the 1910-15 basis shows:

Spokane Street Railway	$4,732,521.00
Interurban System.....................	860,693 00
Lands—Spokane Railway........................	250,761 00
Lands—Interurban	178,692 00
Total..	$6,022,667.00

A calculation of what he thought was a fair system of annual depreciation allowances to be made on the property of the Washington Water Power Co. was presented by Mr. McCurrach, showing:

	Per Cent.	Amount
Spokane Street Railway	3 99	$191,185.00
Interurban railway	3 85	32,613.00
Light and power, Washington.	3 51	480,862.00
Light and power, Idaho	3 49	86,067.00
Total annual depreciation	3 71	$790,727.00

Remember, oil is lazy and very unobliging; it will never accommodate you by working to the center of a bearing, but will always work from the center out.—*Marine Engineering.*

Fuel Conservation by Off-Peak Rates for Isolated Plants

The testimony presented at the resumed hearing before the Public Service Commission for the First District of New York, on May 13, was of a character intended to establish the superiority of the isolated plant over the central station under certain conditions of operation and to bring out the idea that fuel can be saved to a community by permitting isolated plants to purchase current from public-service plants during the nonheating season and generate their own electricity during the heating season.

The plant of Saks & Co., Broadway and 34th St., furnishes light and heat to a seven-story building, as well as steam for operating elevator pumps. For about a year after the building was opened, in 1902, the plant was run to furnish light, heat and power. From December, 1903, to November, 1914, the plant discontinued the generation of electricity and purchased the necessary current for lighting from the Edison company. At the end of this period, however, electric generation in the plant was resumed.

A comparison of the costs of operation in 1913 and 1915 is interesting. In 1913 the purchased current cost $21,000 and the cost of operation of the plant to supply steam for heating and for running the elevator pumps was $17,000, making a total of $38,000. In 1915, with the plant supplying light, heat and power, the total cost of operation was $28,850, representing a saving of $9150 over the expense of operation in 1913.

During the heating season, the exhaust steam from the elevator pumps is sufficient to supply practically two-thirds of the heating, the remainder being made up by live steam. In the nonheating season, there is no way of utilizing the exhaust steam, and consequently it goes to waste. If a summer rate for current could be obtained, equal to or less than the cost of production in the plant, the plant could be shut down in the nonheating period with a resultant saving to the community of about 360 tons of coal. Approximately 180,000 kw.-hr. is needed during the nonheating season, and the generation of this current by the central station instead of the isolated plant could be done on at least 4 lb. of coal less per kilowatt-hour, amounting to a saving of 720,000 lb., or 360 tons. During the heating season, however, the central station would have no such advantage over the isolated plant, as the latter would use its exhaust for heating.

The plant of Bonwit Teller & Co., Fifth Avenue and 38th St., supplies steam for the operation of engines driving electric generators, for running refrigerating machinery and for heating. Comparison of the cost of generating current in this plant, as taken from the plant records, and buying it from the Edison company shows that the former is about half as large as the latter. The reason is that no exhaust steam is wasted, in the heating season, as it can all be used in supplying heat to the seven-story building in which the plant is situated.

The shutting down of the electric-generating part of the plant would have little value as a coal-saving scheme. About 14 tons a day is required for heating, and if current for lighting is generated, the coal consumption is only about 17 tons a day. The number of kilowatt-hours generated, however, is much greater than the central station could produce with the 3 tons of coal representing the increase of coal consumption, because the isolated plant obtains the current as a byproduct of the heating system.

The Columbia Trust Co., 60 Broadway, installed a private electric plant in 1915. Before that time current had been purchased from the Edison company, and an isolated steam plant had furnished the heating and run the elevators. The result is that the electric plant has saved enough to pay for the cost of installation and all interest charges. The saving for the year ending Oct. 15, 1916, was $10,171 and for the year ending Oct. 15, 1917, was $11,396. These savings were calculated on the basis of the Edison rate for current before the electric plant was installed. For example, in the year ending Oct. 15, 1916, the electric current used would have cost $19,494 at the Edison rate. The heating would have cost $7938 more, making a total expense of $27,432. The actual operating expense for that year was $17,261, so the amount saved was $10,171.

Percival R. Moses, who has had a wide experience in designing private plants for buildings, appeared in behalf of the isolated plant. He advocated coöperation of the public-service utility and the isolated plant as the solution of the coal-conservation problem. His plan would be to shut down the private plants during the nonheating season, when they have no use for exhaust steam and could therefore operate only wastefully, and to establish a low rate whereby they could purchase current for lighting during this period from the public-service plants.

The views expressed by Mr. Moses are given at considerable length in an article by him in the Mar. 26, 1918, issue of *Power*. He said in his testimony that the Chicago Edison Co. has established rates for off-peak service to isolated plants during the nonheating season, as follows: 3c. per kw.-hr. for the first 25,000 kw.-hr.; 1.3c. per kw.-hr. for the next 25,000 kw.-hr.; 1.1c. per kw.-hr. for the next 70,000 kw.-hr., and 0.9c. per kw.-hr. for all in excess of the last figure. It was his impression that the City of Milwaukee had a similar off-peak rate.

It will be remembered, in this connection, that at a preceding hearing John W. Lieb, of the New York Edison Co., made the statement that under the conditions existing in New York City there was no such thing as off-peak service, because a sudden demand might arise to tax the entire capacity of a station.

Mr. Moses was asked whether he could account for the paradoxical statement that in some plants less coal was burned for heating and generating current than for heating alone. He said that where live steam was used for heating it was quite probable that too high a temperature was remedied by opening windows; whereas, in a plant using exhaust steam for heating, the supply available is only that which comes through engines and pumps, at a fairly uniform rate, and therefore there is likely to be less waste of heat because of excessively high temperatures.

The hearing was adjourned until June 10, 1918.

Record Coal Production

A week's record production of bituminous coal is indicated by reports received by the United States Fuel Administration covering the week ended Apr. 27. During that week the total output is estimated by the United States Geological Survey at 11,803,000 net tons, an increase of 6.1 per cent. over the preceding week. The average production per working day was 1,946,000 net tons compared to 1,840,000 net tons the previous week and 1,680,000 net tons during April, 1917.

The output for the month of April, 1918, is estimated at 36,478,000 net tons, an increase of 10 per cent. over April, 1917. Production for the four months ended April, 1918, is estimated at 181,992,000 net tons, an increase over 5,000,000 net tons, or about 3 per cent. over the same four months of 1917. The week ended Apr. 27 recorded not only the highest rate of production for the past 12 months, but was the third successive week of rising production. The reports to the U. S. Geological Survey showed a gradual improvement in car service conditions at the mines during the week ending Apr. 20. Loss of production due to car shortage throughout the country was reported as 16.2 per cent. as against 18.1 per cent. for the preceding weeks. Loss due to labor shortage was 4.8 per cent. as against 2.6 per cent. during the preceding weeks.

There is quite a loss due to "no market" all through the Middle West, the loss running from 5.8 per cent. for the Rocky Mountain States to 30.7 per cent. for mines in Iowa.

During the week ended May 4 bituminous output declined slightly after three successive weeks of rising production, the total production being estimated at 11,559,000 net tons, a decrease of 2 per cent. from the week previous.

The continuous rotary motion of the turbine is ideal for certain drives, but the crank is still the ideal drive for an air compressor, as it gives the mechanical advantage of power application just when it is needed.—*Marine Engineering.*

Changes in Coal-Zoning Plan

Under an order modifying the zone system issued by the Fuel Administration, bituminous coal originating on the Broad Top Mountain railroads and their short-line connections, in the States of Pennsylvania, West Virginia and Maryland, when routed via the Pennsylvania R.R., is embargoed from Baltimore and Washington markets.

To meet this situation the Fuel Administration will arrange for the essential supply to the points designated from mines on the Baltimore & Ohio, the Western Maryland and their connections, which lines afford a much more direct route to these points. As a consequence a vast amount of time and mileage will be saved to the Pennsylvania lines, thus assuring an increased movement of coal to points in eastern Pennsylvania, New Jersey and New England.

Consumers of the classifications named in Preference List No. 1, of the priority board, will receive coal in preference to any other individual or class of consumers.

Under the modified order, which became effective on Apr. 20, producers in the sections named will be prohibited from selling, shipping or distributing coal to dealers and consumers at Washington and Baltimore and at all stations on the Baltimore & Sparrows Point R.R. when routed via the Pennsylvania.

The order forbids the shipment of bituminous coal over the railroads named for railroad delivery or transshipments to vessels in Baltimore, at President Street, Highlandtown, Jackson's Wharf, Calvert, Bolton, Frederick Road and Gwynns Run station; and points of delivery between any two of such stations; all stations and points of delivery on the Baltimore division of the Pennsylvania R.R. from Loudon Park, Md., to Catonsville, Md., inclusive, and Arbutus, Md., to Washington, D. C., and Rosslyn, Va., including Popes Creek branch, running from Bowie, Md., to Popes Creek, Md., inclusive.

Consumers located on the Pennsylvania and Baltimore & Sparrows Point railroads will continue to receive their coal at their regular points of delivery, the coal moving via the Baltimore & Ohio and Western Maryland being delivered to the Pennsylvania at junctions near destinations.

Navy Steam Engineering School

The United States Navy Department has perfected plans for the enrollment and training of considerable numbers of engineering officers. A school for this training known as the United States Navy Steam Engineering School, has been established at the Stevens Institute of Technology, Hoboken, N. J., under the guidance of Dean F. L. Pryor as Civilian Director.

The course consists of five months' training divided as follows: One month of military training at the Naval Training Camp, Pelham Bay Park, New York; one month at the U. S. Navy Steam Engineering School; two months' practical training on board ships and in repair shops in the vicinity of New York; one month finishing course at the U. S. Navy Steam Engineering School.

The school is open to men between 21 and 30, who are physically qualified, of thorough ability and officer-like character, and who have completed the engineering course at any recognized technical school.

This school presents particularly desirable opportunities to the young technical man, both in affording him a proper outlet for his trained facilities during the war and in rounding out his college work with a practical course and school experience which will be of value to any engineer.

The service that a graduate from the school will perform will be that of an engineer-officer in the auxiliary service of the Navy. A graduate of the school will be commissioned an ensign in the Naval Reserve Force.

Information has been sent to all registered technical schools and should be on file at the President's office. For any additional details application can be made to the Civilian Director, U. S. Navy Engineering School, Stevens Institute, Hoboken, N. J.

Any men, graduates or undergraduates, who are registered in the draft can enroll with the proper enrolling officer by securing from the draft board a letter of release, which in all probability can be obtained for this purpose, provided the men are not included in the current draft quota.

Special provision has been made for the continuance of the school with proper material by a Navy regulation which permits undergraduates of the freshman, sophomore and junior classes in recognized engineering schools to enroll in the Navy with a rating seaman second class and continue their courses at the institutions where they have matriculated. Such men will be called into active service after their graduation and can at that time, if they are physically qualified to pass an officer's physical examination, enroll for the course at the United States Navy Steam Engineering School.

Trained Engineers for Naval Service

The Bureau of Navigation, Navy Department, is desirous of securing trained engineers for general service in the Navy in steam and electrical engineering and radio duties.

Applicants will, if accepted, be enrolled as ensigns in the Naval Reserve Force and will be sent to the reserve officers' school at Annapolis for a special course of about four months, after which those who finish this course successfully will be placed in further training ashore or afloat, and then become available for regular sea or shore duty as the exigencies of the service may demand.

Applicants for this general service should have the following qualifications: A degree in mechanical, electrical or mining engineering, conferred by a college of recognized standing; at least two and one-half years' practical engineering experience subsequent to graduation (exclusive of time spent as sales agent); not over thirty-five years of age; physically strong and sound in health.

The American Institute of Electrical Engineers, American Institute of Mining Engineers, American Society of Mechanical Engineers, Naval Consulting Board and National Research Council have each been requested to submit a list of fifty names equally proportioned among personnel trained in steam-engineering duties, electrical-engineering duties and radio duties; but the exact engineering duties to be performed in general service by each applicant will be decided after completion of the training under Naval supervision.

It is probable that from among the applicants selected, a class will be formed at the Naval Academy about the middle of June. Each applicant should without delay forward to the Engineering Council, which is acting for the five organizations named, a résumé of his education and engineering experience, together with a small photograph, if practicable, and such letters of recommendation as it may be possible to submit, addressed to 29 West 39th St., New York City.

Government Wants Business Diplomats

The Government is looking for big-caliber men with foreign trade experience to serve as commercial attachés for the Bureau of Foreign and Domestic Commerce, Department of Commerce, and announces that appointees will be accredited to American embassies or legations abroad and will be expected to meet in a creditable manner the most important Government officials and business men in such countries and make trade reports. A rigid examination will be held on June 6, and those interested are urged to write at once to the Bureau of Foreign and Domestic Commerce, Washington, for further details.

The salary of the Commercial Attachés ranges from $4000 upward, and there are transportation and other allowances. The Department of Commerce is also planning to appoint trade commissioners to Europe, South Africa and the Far East in the near future.

Many engineers forget, or never knew, that in a nonreversing engine only one side of the crankpin gets any wear. Think this statement over, and you will find it true.—*Marine Engineering.*

Maximum Production with Minimum Waste

The United States Fuel Administration has announced the appointment of Thomas R. Brown, of Pittsburgh, as administrative engineer for the Pittsburgh district, and C. P. Billings as special staff assistant. These appointments were made as a preliminary step toward putting into operation a general plan for fuel conservation in power plants.

This plan is the result of conferences with the Federal Fuel Administrators and their committees for the group of states which together consume about 70 per cent. of all the coal used in the United States, exclusive of railroads. The plan has received the indorsement of the fuel administrators of all these states, as well as the approval of the United States Bureau of Mines and a committee representing the Engineering Council of the four national engineering societies.

The slogan of the campaign is "Maximum production with minimum waste." In other words, the object is to operate all industries at full capacity, but at the same time to make a pound of fuel perform its maximum service in power, light and heat.

In laying the foundations for the organization it has been anticipated that this work should become a permanent service of the Government.

Ten to twenty per cent.—that is, from 25 to 50 million tons of coal per year—can be saved by the correct operation of steam power plants, using their present equipment, in the industries, in office buildings, hotels, apartment houses, etc.

It is considered most important that all existing fuel-conservation committees, committees of chambers of commerce and national defense, manufacturers' associations, and other bodies be continued in full force, and that the work of such organizations be consolidated with the national program, which comprises certain fundamentals as follows:

Fundamentals of the Program

Personal inspection of every power plant in the country.

Classification and rating of every power plant, based on the thoroughness with which the owner of the plant conforms to recommendations.

Responsibility of rating the plants will fall upon an engineer in each district, the rating to be based on reports of inspectors, who will not express opinions, but will collect definite information. The State Fuel Administrator, in his judgment, may entirely or partially shut off the consumption of coal to any needlessly wasteful plant in his territory.

Inspectors are to be furnished from one or more of the following sources: Inspectors of the steam-boiler insurance companies; state factory inspectors; engineering students from technical colleges; volunteers.

The ratings will be based on recorded answers to questions, each of which will be given a value depending upon its relative importance to the other questions. Depending on the efficiency of methods in use in any plant, it may be rated in Class 1, 2, 3 or 4.

The ratings will be based on existing equipment. The difficulty, delay and expense involved in the installation at this time of improved power equipment is fully recognized, but experience has proved that 10 to 20 per cent. of fuel now used in power plants can be saved by improvements in operation alone.

In advance of the first inspection a questionnaire will be sent to every power plant in each district, with notice to the owner that within 60 or 90 days his plant will be inspected personally and the questionnaire will be checked up by the inspector upon his visit. This action will tend to prepare the minds of plant owners for what will follow. It will operate to induce proper care in furnishing information and will also tend to produce a desire to improve their plants, if necessary, so that they may be rated in a high class by the time the inspector calls.

It is recommended that a board of competent engineers be attached to the conservation committee in each state; also a corps of lecturers to arouse public interest and disseminate engineering information.

The Fuel Administration has prepared a 50-minute film of moving pictures showing good and bad operation in the steam-boiler plant, methods of testing boilers, fuels, etc. These pictures will be available for each state in connection with its educational propaganda.

The administration is also preparing a series of official bulletins on engineering phases of steam and fuel economies. Some of these are now ready for printing. They will include: Boiler and Furnace Testing; Flue Gas Analysis; Saving Steam in Heating Systems; Boiler-Room Accounting Systems; Saving Steam and Fuel in Industrial Plants; Burning Fine Sizes of Anthracite; Boiler Water Treatment; Oil Burning; Stoker Operation.

In addition to this service a list of competent engineers has been prepared in Washington for each state and is available for use of each local administration. As the work develops, still further constructive assistance is contemplated for helping owners to bring their plants up to a high plane of economic operation.

Opposing Hun Force with Engineering Intelligence

Preparations by American engineers for leadership in the coming industrial development of Russia are being urged by the Russian Society of Engineers of Chicago. This organization was formed to help introduce modern achievements of American engineering into Russia and to develop friendly relations between the two countries. These aims are of special importance at the present time, as Russia is beginning to emerge from its chaotic conditions and to show increased resistance to the German invaders. To strengthen this resistance means to keep the vast natural resources of Russia from falling into the hands of Germany. This as well as the great prospective market into which Russia will ultimately develop should interest the American business man and especially the engineer who is the modern industrial pioneer. To promote this work a series of lectures by Russian and American engineers on the industrial needs of Russia and the mutual benefits to be derived by commercial intercourse is being arranged for all Chicago engineers by the society.

With a spirit of coöperation in this international patriotic endeavor the Western Society of Engineers is in accord, and the first meeting will be held May 22 in its rooms. W. J. H. Strong, Strong Engineering Co., will talk on "Industrial Developments in America as Compared With Those in Russia," and W. W. DeBerard on "Engineering Publicity." The Young Men's Committee of the latter society has already begun to study international subjects intensively, having spent two nights on the "Situation in Colombia, South America," and one on "Russia."

It is certain that the American engineer's horizon will not be to the boundaries of the United States hereafter, and studies of foreign development problems must be undertaken if the engineer is to keep in the foreground of obvious opportunities.

Control Over Power Companies

Upholding an order of the New York Public Service Commission, Second District, restraining the Oneonta Light and Power Co. from continuing to operate within certain territorial limits in Otsego County, N. Y., the Appellate Division of the New York Supreme Court holds that where an electric-power company's charter makes its right to exercise its powers within the limits of a town, village or city conditional upon obtaining the consent of the municipal authorities, there is no right to do business within such limits in the absence of such consent, although the owners of private property to be served consent to the stringing of poles, wires, etc., across their property. It is further decided in the same case that the fact that an electric-power company may acquire a private right-of-way for its transmission lines does not defeat supervisory control of the construction work by the Public Service Commission. (167 New York Supplement, 486.)

Frederick Remsen Hutton

IT IS with deep regret that we announce the death of Frederick Remsen Hutton, well-known engineer, educator, and distinguished member of the American Society of Mechanical Engineers, at his home, New York City, Tuesday, May 14. Death was due to heart trouble.

Professor Hutton was born in New York City, May 28, 1853; he died in his sixty-fifth year. After preparation in a private school, he entered Columbia University, receiving the degree of A. B. in 1873. After graduation he entered the School of Mines and was given its degree in 1876. Later he became an instructor, and was assistant to the late Professor Trowbridge, entering the faculty as adjunct professor in 1881 and professor in 1890. Professor Hutton served as head of the department of mechanical engineering until his resignation in July, 1907, when he was elected professor emeritus. From 1899 to 1905 he was Dean of the Schools of Engineering.

In 1911 he served as consulting engineer to the Department of Water, Gas and Electricity, New York City, and from 1905 to 1911 was vice chairman of the Museum of Safety. He was consulting engineer to the Automobile Club of America and chairman of its Technical Committee since 1912, in which capacity he supervised the important testing work conducted by the club in its laboratory.

It is as a member of the American Society of Mechanical Engineers that Professor Hutton was most widely known. He was made president of that society as the culmination of twenty-four years of service as its secretary. He had the honor of presiding at the first meeting of engineers in the splendid auditorium of the Engineering Societies Building in 1907. He represented the American Society of Mechanical Engineers at the formal ceremonial days of the dedication of the new building, a noteworthy event in the annals of American engineering society history. It was in 1883 that Professor Hutton became secretary of the A. S. M. E., three years after its organization. The offices were then at 17 Cortlandt St., and more than once in those early days he paid the office rent out of his own pocket.

FREDERICK REMSEN HUTTON

Professor Hutton was of great influence in giving international recognition to the society. He was connected with arrangements of the European trip in 1889, one of the noteworthy events in the society's history. He was a member of the Conference and Building Committee of the United Engineering Society which planned the present Engineering Societies Building at 29 West 39th St.; he also was one of the Board of Trustees holding the corporation for the United Engineering Society, 29 West 39th St., New York City.

Professor Hutton contributed much to scientific literature. His most important books are: "The Mechanical Engineering of Power Plants," "Heat and Heat Engines" and "The Gas Engine." The first is used as a textbook in some of the technical institutions of Japan. He contributed considerable to encyclopedias, dictionaries and the technical press. His speech at Washington before the American Uniform Boiler Code Congress early last year struck a new note in industrial-governmental relationship. Although an individualist by theory and preference, he recognized that the growing complexity of the social fabric would sooner or later compel significant changes in the relation of individuals, corporations and the state. At this congress he pointed out that a boiler explosion was a community loss, and not alone a loss to the purchaser, builder and insurance company.

He supplemented this speech with an article published in *Power* for June 5, 1917, p. 774, and in this he asked the significant question: "—— is there any logical pausing stage before the community demands economy and efficiency in the use of increasingly precious fuel in the generation and distribution of power, with a view to lowering the cost to the community of such commodities as call for power in their production?"

To quote further from this article: "First, every machine (and a power-house boiler and engine and generator are in this class) should be functioning continuously if possible, to earn the interest on its cost and pay the proper share of overhead charges. Second, an accident that involves the machine or disables its operator, or both machine and operator, breaks into this continuity of earning and involves losses. These losses fall into several groups: First, the cost of repair; second, the losses of idleness; third, the costs of compensation for bodily injuries, or of insurance against this cost; fourth, the costs in wasted stock and defective work, due to teaching a new operator, also in the slow and inferior production of the worker as yet inexpert; and fifth, the costs of the slackened speed of all workers in the department while the memory of it is fresh in the minds of those who witnessed the accident. There are, furthermore, indirect losses from the accident, which reach the community only through the heavy losses borne in the narrow circle affected when its wage-earner is disabled."

Among the societies and clubs to which Professor Hutton belonged are the Engineers' Club, New York, and the New York State Society of Cincinnati.

Final Figures for Rainbow Division

Final figures for the Rainbow Division given out by the Advisory Trades Committee of the Liberty Loan Committee, May 11, showed that the total subscriptions for all the 86 business and professional organizations comprising this division was $564,767,950. The grand total for the Second Loan was $409,367,150.

At the beginning of the Third Loan, an allotment of $450,000,000, one-half the total for the entire Second Federal Reserve District, was given the Rainbow Division. During the first two weeks of the campaign it looked as if the Division was falling behind the schedule laid out by the Central Committee. Emergency meetings were held and an intensified plan of action was begun.

One week after this, on Apr. 27, the total for the Second Loan was passed and on May 3 the figure aimed for, $450,000,000, was also passed.

Seventy committees reached and passed their total for the Second Loan. Of these the one that made the greatest percentage increase was the Electrical Committee. Its total for the Second Loan was $809,000 and for the Third, $9,457,000. This committee was awarded an Industrial Bull's-eye Honor Flag containing 21 stars, each star indicating an increase of 50 per cent. over the preceding total.

Standing out as one of the best things in the entire campaign was the splendid support of the workers. Not only did the employees buy in greater amounts and in larger numbers than in the two preceding loans, but the labor unions gave their fullest support and also bought more bonds than ever before.

How well the men and women workers supported the Third Loan can be seen by the fact that fully 5000 Industrial Honor Flags were awarded to firms where 60 per cent. and more of their employees bought the third issue of bonds. Nearly 1500 of these were 100 per cent. flags, meaning that every worker in each factory, firm and company bought a bond. It is expected that the total of 100 per cent. flag winners may reach and pass the 2000 mark when all the applications have been received and verified.

Personals

Frederick Ray, consulting engineer, announces the removal of his office from 95 Liberty St. to the Mills Building, 15 Broad St., New York City.

Cyrus Garnsey, Jr., has been appointed assistant fuel administrator. He will be in general charge of the administrative work of the Fuel Administration.

J. M. Riordan, until recently sales engineer of the Grant Lees Gear Co. of Cleveland, and formerly representing the Fellows Gear Shaper Co., of Springfield, Vt., in the Central States, is now connected with the sales organization of the Cleveland Milling Machine Co., 18,511 Euclid Ave., Cleveland, Ohio.

John A. Stevens and associated engineers, of Lowell, Mass., were presented the medal by the National Association of Cotton Manufacturers, at the Hotel Biltmore, New York, on May 3, for their paper on "The Evolution of the Steam Turbine in the Textile Industry," presented at the annual meeting of the association which was held in Boston, Apr. 25-26, 1917.

Engineering Affairs

The International Railway Fuel Association will hold its tenth annual convention at the Hotel Sherman, Chicago, May 23-24. Representatives of the United States Railroad Administration and the United States Fuel Administration will take a large part in the activities.

The New York Chapter of the American Association of Engineers will hold its annual election of officers at the Hotel McAlpin on May 22, at 8 p.m. G. A. Harris, chief engineer of the American Steel Export Co. will deliver an address on "The Opportunities for the American Engineer in the Export Field."

The Society for Electrical Development, Inc., held its annual meeting on Tuesday, May 14, at the offices of the society in New York. James R. Strong presided. The general manager read his annual report, reviewing the work of the society during the past year and suggesting activities for the coming year. At the Board of Directors' meeting which followed the annual meeting, it was decided to continue the work of the society for another year upon the present basis and to conduct a "Convenience Outlet" campaign as suggested by the general manager. An appropriation was made to carry on the campaign along national lines, similar to the "Wire Your Home" and "America's Electrical Christmas" campaigns. The officers elected for the ensuing year were: Henry L. Doherty, reëlected president; Joseph E. Montague, vice president and as a member of the executive committee; Gerard Swope, chairman of the executive committee; James M. Wakeman, reappointed general manager; James Smleton, Jr., secretary and treasurer.

Miscellaneous News

A High-Pressure Steam Pipe exploded in the testing room of the Sturtevant Blower Works at Hyde Park, Mass., on May 9, killing one man and injuring three others. The men were testing a turbine engine, forcing steam into it through a pipe 2½ in. in diameter, which broke, one section of it going through the wall of the building.

Business Items

The Brown Instrument Co., of Philadelphia, will open a new office at 2086 Railway Exchange Building, St. Louis, June 1, in charge of Paul H. Berggreen.

The Lehigh Foundry Co. and the Lehigh Car, Wheel and Axle Works, of Fullerton, Penn., have been merged into one organization to be known as the Fuller-Lehigh Co., with office and works at Fullerton. The properties of the two companies are adjoining and have been under the same management for a number of years. The change therefore is one of name only, the executive personnel remaining the same. J. W. Fuller is president.

The Joseph Dixon Crucible Co. at its annual and regular meetings on Apr. 15 elected the following directors and officers: Directors: George T. Smith, George E. Long, William G. Bumsted, Edward L. Young, J. H. Schermerhorn, Harry Dailey, Robert N. Jennings. Officers: George T. Smith, president, George E. Long, vice president, J. H. Schermerhorn, vice president, Harry Dailey, secretary, William Koester, treasurer, Albert Norris, assistant secretary and assistant treasurer. The American Graphite Co., Inc., is a subsidiary of the Joseph Dixon Crucible Co. and on the same day elected the following officers: George T. Smith, president, George E. Long, vice president, J. H. Schermerhorn, treasurer, Harry Dailey, secretary. The directorate is the same as that of the Joseph Dixon Crucible Co.

NEW CONSTRUCTION

Proposed Work

N. H., Manchester—The Manchester Traction Light and Power Co. is receiving bids for the erection of a 25 x 45 ft. addition to its power house. F. W. Gray, Elm St., Arch. Noted May 14.

Mass., Boston—The Board of Education will receive bids until May 24 for the installation of a heating system in 2 schools. About $10,000.

Mass., Canton—The Springdale Finishing Co., Pine St., will build a 2 story, 45 x 50 ft. reinforced concrete, steel and brick power house. Estimated cost, $25,000. Noted Apr. 30.

Mass., Dedham—The Cochrane Manufacturing Co., 56 Barrett Ave., Malden, will soon receive bids for the erection of a power house, transmission line and dam here. E. Worthington, Engr.

N. Y., Buffalo—The Buffalo Cereal Co., Chamber of Commerce, is having plans prepared for the erection of a 40 x 40 ft. power house in connection with its new plant.

N. Y., Buffalo—The Lamoka Electric Water Power Corporation has been given a franchise by the State, permitting it to use the waters of Little and Lamoka Lakes to generate electric power.

N. Y., New York—The B. L. M. Bates Corporation, Hotel Belmont, is in the market for boilers and superheaters. Estimated cost between $66,000 and $70,000. Warren & Wetmore, 16 East 37th St., Arch.

N. Y., New York—The United Electric Light and Power Co., 130 East 15th St., has purchased a site and plans to build an electric power station. J. G. Swallow, Supt.

N. Y., Olean—The Olean Electric Light and Power Co. plans to purchase additional equipment. F. G. Tennant, Gen. Supt.

N. Y., Schenectady—The American Locomotive Co., North Jay St., is having plans prepared for the erection of a 120 x 175 ft. addition to its boiler house.

N. Y., Syracuse—The Syracuse Lighting Co. is having plans prepared for the erection of an electric lighting plant on South Warren St.

N. J., Bayonne—The Elco Works, Ave. A and North St., plans to build a new power plant and install equipment including 2 direct connected engines, 400 hp. each; direct current generators, 250 kw., 25 volts with four 250 hp. boilers, etc.

N. J., Mays Landing—The Bethlehem Loading Co. will build a power plant near the South River in connection with its plant. C. J. Sittinger, Power Engr.

N. J., Ogdensburg—The New Jersey Zinc Co. plans to build a 1 story power house here. Estimated cost, $15,000. A. Lee, 55 Wall St., New York City, Purchasing Agent.

N. J., South Plainfield—The Spicer Manufacturing Co. has plans under consideration for the erection of a new power house in connection with its plant.

Penn., Bethlehem—The Bethlehem Electric Co. plans to issue $50,000 bonds; the proceeds will be used to build additions and make improvements.

Penn., Elwood City—The Pennsylvania Power Co. has purchased a 5 mile site on the water front in the Turkey Hill section, and plans to build a dam. L. B. Round, Supt.

Penn., Philadelphia—J. Bromley & Sons has awarded the contract for the erection of additions and improvements to its boiler plant at Front and Dauphin St., to G. W. Stewart & Co., 2123 Germantown Ave.

Penn., Philadelphia—City will soon award the contract for improvements to its power plant. W. H. Wilson, Director of Public Safety.

Penn., Pittsburgh—The Pittsburgh Modern Laundry Co. is having plans prepared for the erection of a new power plant in connection with its proposed plant. Estimated cost, $60,000. P. W. Irwin, Renshaws Bldg., Arch.

Penn., Wescoesville—The Commissioners of Lehigh County are considering the erection of a boiler plant. T. Moyer, 824 Hamilton St., Allentown, Arch.

N. C., Gibsonville—The Gibsonville Milling Co. plans to build an electric power system from here to Summers Mill.

N. C., Gliden—R. O. Blanchard is in the market for electrical and water power machinery.

La., Ville Platte—The Town will receive bids until June 4, for the erection of an addition to its electric lighting plant and line. Estimated cost, $5000. Work will include the installation of a 35 kw. alternator, setting 1 motor driven pump, switchboard, series lighting transformer and regulator, moving and repairing 1 Mietz and 1 Weiss engine and General Electric generator. Address A. C. Jones, Opelousas, La.

Tenn., Rutherford—City voted to issue $10,000 bonds for the installation of an electric lighting plant.

Ohio, Cincinnati—The Union Gas and Electric Co. plans to install a third generating unit.

Ohio, Marion—The Delaware and Marion Ry. Co. has geen granted a franchise by Marion Co. Commissioners, to erect a 10-mile transmission line from here to Caledonia.

Ohio, Youngstown—The Hydraulic Gas Power Co. has increased its capital stock from $200,000 to $300,000; the proceeds will be used to build additions to its plant.

Ill., Chicago—C. A. Brown, c/o C. E. Frazier, 30 North Darhorn St., is in the market for a low pressure steam heating plant for its truck body factory on 35th and Shields Sts.

..**Ill., Chicago**—The Chicago United Theaters Incorporated, c/o W. W. Alschuler, Arch., 111 West Washington St., plans to install a low pressure steam plant in its 2 story, 136 x 150 ft. theater on 63rd and Union Sts.

Wis., Milwaukee—City is in the market for one 125 brake hp. alternate current motor and one 20 in. centrifugal pump. Estimated cost, $2000.

Minn., Caledonia—The Root River Power and Light Co., Preston, plans to extend its electric system from here to Houston. A. H. Hanning, Preston, Mgr.

Kan., Baxter Springs—E. D. Nix, L. D. Knight and C. M. Mitchell, mine owners, plan to install equipment in their zinc mine. The installation includes engines, boilers, etc. C. M. Mitchell, Supt.

Kan., Wichita—The St. Francis Hospital is having plans prepared by E. Forsblom, Arch., 403 Winne Bldg., for the erection of a 2 story, 49 x 68 ft. power house and laundry. Estimated cost, $20,000.

Mont., Scoby—School District No. 1 will receive bids about June 15, for the installation of a heating plant here. Estimated cost, $15,000.

Mo., Seneca—The Oklamo Mining Co. plans to install engines, boilers, etc., in its lead mine. C. B. Bettis, Joplin, Pres. C. T. Jobes, Supt.

Ark., Lamar—The Peoples Service Co., 312 Barnes Bldg., Muskogee, Okla., has secured a franchise to establish an electric lighting plant here.

Tex., Del Rio—City plans to install an electric lighting plant.

Okla., Jennings—City voted to issue $25,000 bonds for the installation of an electric lighting plant. Noted May 14.

Okla., Miami—City plans to build a power and water plant. Estimated cost, $250,000. Bids are now being received for the new equipment for same.

N. M., Portales—City plans an election soon to vote on $20,000 bonds for the erection of an electric light and power plant. W. H. Braley, Clerk.

Ariz., Nogales—The Arizona Gas and Electric Co. has petitioned the State Corporation Commission for authority to issue $100,000 bonds; the proceeds will be used for the installation of an additional generating unit, etc.

Ore., Klamath—The Pacific Gas and Electric Co., 445 Sutter St., San Francisco, Calif., the Northern California Power Co. and the California Oregon Power Co. plan to build a 300 mi. transmission line from the Klamath River plant of the California Oregon Power Co. to San Francisco bay district. This work and many other improvements will cost about $1,000,000.

Ont., Bridgeburg—The Board of Education plans to install a heating system in the Phipp Street school. An appropriation for $10,000 is before the aldermanic board for same.

Sask., Regina—A. Beach, City Clerk, is in the market for electrical equipment for lighting. About $200,000 will be expended.

CONTRACTS AWARDED

R. I., Pawtucket—F. W. Taylor, 438 Main St., has awarded the contract for the erection of a 1 story, 65 x 80 ft. boiler house in the rear of Oak Hall Bldg., to J. W. Bishop Co., Butler Ex.; 4 new boilers will be installed.

N. Y., Albion—The Western House of Refuge has awarded the contract for the erection of an addition to its boiler plant, to H. C. Belson, Albion.

N. Y., Brooklyn—The Arabol Manufacturing Co., 100 William St., New York City, has awarded the contract for the erection of an addition to its boiler plant, to J. H. Deeves & Bro., 103 Park Ave., New York City. Noted Mar. 19.

N. Y., Brooklyn—The Brooklyn Gas Co., 176 Remsen St., has awarded the contract for the erection of a 30 x 40 ft. addition to its boiler plant, to J. H. Deeves & Bro., 103 Park Ave., New York City.

N. Y., Brooklyn—The Flatbush Gas Co., Clarkson St. and Kingston Ave., has awarded the contract for a 1 story, 30 x 40 addition to its boiler house, to J. H. Deeves & Bro., 103 Park Ave., New York City.

N. Y., New York—The Interborough Rapid Transit Co., 120 Bway., is building a transformer station on East 57th St. Estimated cost, $45,000.

Penn., Philadelphia—The Germantown Steam Heating Co., has awarded the contract for alterations and additions to its power house on Pelham Rd. and Hortter St., to W. O. Springer, 349 West Hortter St.

Penn., Philadelphia—The Philadelphia and Reading R.R., Reading Terminal, has awarded the contract for the erection of a 1 story, 44 x 78 ft., brick, concrete and steel power house at Tulip and Somerset St., to Pringle Borthwick, 8018 Germantown Ave. Estimated cost, $30,000. Noted Nov. 27.

Md., Baltimore—Roberts Bros., Wolfe and Preston St., has awarded the contract for the erection of a cannery, to P. J. Cushen, 117 St. Paul St. Estimated cost, $13,065. The work includes the construction of a boiler house, warehouse, etc.

Ohio, Akron—The Wellman Seaver Morgan Co., 260 Kenmore Blvd., has awarded the contract for the erection of a power house, to the G. A. Fuller Co. Estimated cost, $30,000.

Ohio, Columbus—The U. S. Government has warded the contract for the erection of the Columbus Quartermaster Interior Depot, to Hunkin Conkey Co., 321 Cuyahoga Bldg., Cleveland. The work includes the erection of an electric light and power plant, etc.

Ill., Chicago—P. J. Hursen, 4446 West Madison St., has awarded the contract for the erection of an undertaking establishment to McCarty Bros., 10 South La Salle St. A new steam heating plant will be installed.

Ill., Chicago—The Illinois Central R.R. has awarded the contract for the erection of a new electric power plant at 98th St. and Cottage Grove Ave., to J. E. Nelson & Sons, 118 La Salle St. Estimated cost, $60,000.

Neb., Falls City—City let contract building 1 story, 50 x 110 ft. power house, to Bohrer Bros., Falls City. Noted Feb. 8.

Que., Drummondville—The Southern Canada Power Co., on St. Francis River, has awarded the contract for the erection of a power house and dam, to Morrow & Beatty, Ltd., Peterboro. Work includes the erection of an 80-mile transmission line.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular Current	Individual Current
Buckwheat	$4.60	$7.10—7.35
Rice	4.10	6.65—6.90
Boiler	3.90	....
Barley	3.60	6.15—6.40

BITUMINOUS

Bituminous not on market.

Pocohontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.00 a year ago.

*All-rail to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* are as follows:

ANTHRACITE

	Circular Current	Individual Current
Pea	$4.90	$5.65
Buckwheat	4.45@5.15	4.80@5.50
Barley	3.40@3.65	3.80@4.50
Rice	3.90@4.10	3.00@4.00
Boiler	3.65@3.90	....

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Gross	Mine Price Net	Gross
Central Pennsylvania	$5.06	$3.05	$3.41
Maryland—			
Mine-run	4.84	2.85	3.19
Prepared	5.06	5.05	3.41
Screenings	4.50	2.55	2.85

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty, Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The rate to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Current	One Yr. Ago	Current	One Yr. Ago
Pea	$3.45	$3.00	$4.35	$3.90
Barley	2.15	1.50	2.40	1.75
Buckwheat	3.15	2.50	3.75	3.40
Rice	2.65	2.00	3.65	3.00
Boiler	2.45	1.80	3.55	2.90

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes	$2.65—2.80	$3.35—3.50
Mine-run	2.40—2.55	3.10—3.25
Screenings	2.15—2.30	2.85—3.00

Smokeless Coals	So. Ill., Pocohontas, Pennsylvania and W. Va.	Hocking, East Kentucky and West Va. Splint
Prepared sizes	$2.60—2.85	$2.85—3.35
Mine-run	2.40—2.60	2.60—3.00
Screenings	2.10—2.55	2.35—2.75

St. Louis—Prices per net ton f.o.b. mines are as follows:

	Williamson and Franklin Counties	Mt. Olive & Staunton	Standard
6-in. lump	$2.65-3.00	$2.65-2.80	$2.65-2.80
2-in. lump	2.65-3.00	2.65-2.80	2.25-2.50
Steam egg	2.65-2.80	2.35-2.50	2.25-2.40
Mine-run	2.45-2.60	2.45-2.60	2.45-2.60
No. 1 nut	2.65-3.00	2.65-2.80	2.65-2.80
2-in. screen	2.15-2.40	2.15-2.40	2.15-2.40
No. 5 washed	2.15-2.50	2.15-2.35	2.15-2.35

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump & Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona	2.15	2.40	1.90
Black Creek, Cababa	2.40	2.65	2.15

Government figures.

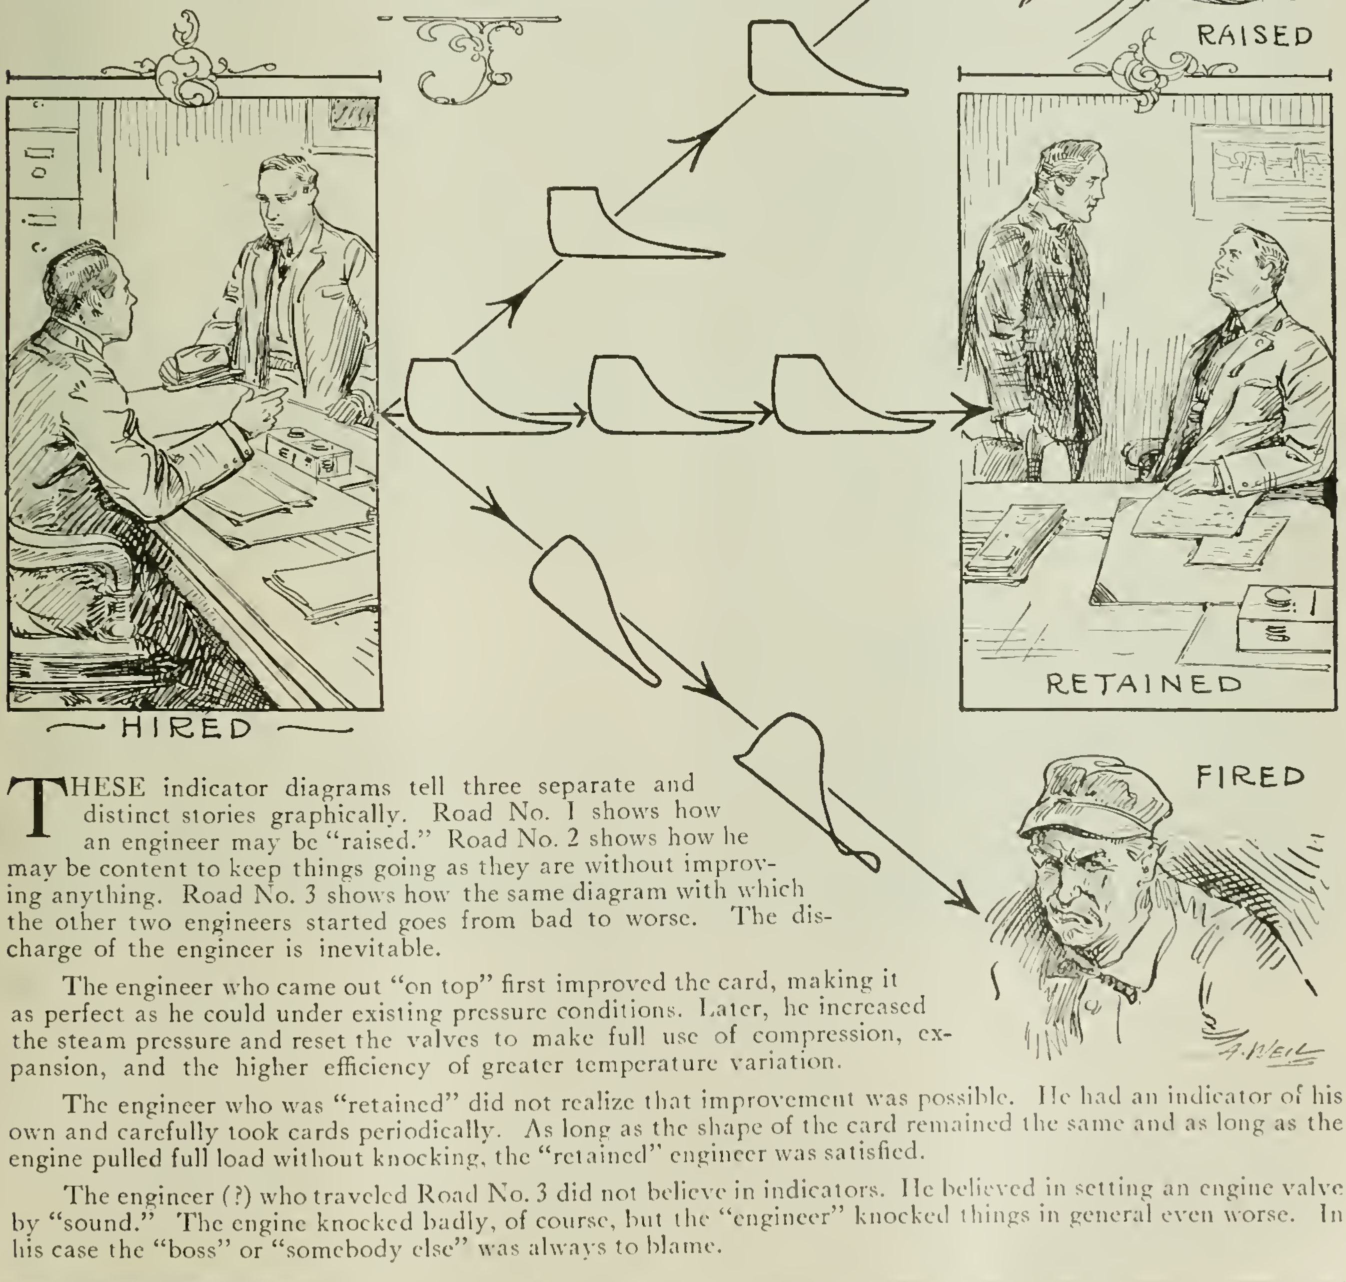
Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

POWER

Vol. 47 NEW YORK, MAY 28, 1918 No. 22

Three Roads

By N. G. NEAR



THESE indicator diagrams tell three separate and distinct stories graphically. Road No. 1 shows how an engineer may be "raised." Road No. 2 shows how he may be content to keep things going as they are without improving anything. Road No. 3 shows how the same diagram with which the other two engineers started goes from bad to worse. The discharge of the engineer is inevitable.

The engineer who came out "on top" first improved the card, making it as perfect as he could under existing pressure conditions. Later, he increased the steam pressure and reset the valves to make full use of compression, expansion, and the higher efficiency of greater temperature variation.

The engineer who was "retained" did not realize that improvement was possible. He had an indicator of his own and carefully took cards periodically. As long as the shape of the card remained the same and as long as the engine pulled full load without knocking, the "retained" engineer was satisfied.

The engineer (?) who traveled Road No. 3 did not believe in indicators. He believed in setting an engine valve by "sound." The engine knocked badly, of course, but the "engineer" knocked things in general even worse. In his case the "boss" or "somebody else" was always to blame.

WORCESTER is the home of two past presidents of the society, namely, Charles H. Morgan and Dr. Ira N. Hollis. The city owes its place as a manufacturing center to the several buildings where power was furnished to tenants who eventually built factories for themselves in the city as their business grew. Some of these old buildings are still standing, and from one of them the other day an old Corliss engine, built in 1852, was removed. The Worcester Polytechnic Institute was started with the assistance of John Boynton, who made his money as a peddler and who contributed liberally to the fund that built old Boynton Hall. The lock system of the Panama Canal is said to be patterned after the locks in connection

with Clinton Dam, near Worcester, which those attending the meeting will visit. Worcester has high- and low-pressure water systems, both of the gravity type; high-pressure, 150 lb., low pressure 85 lb. Camp Deven is but twenty-six miles from Worcester and is one of the large army cantonments. Worcester's population is 200,000, and 3,000,000 people are within fifty miles.

The Fuel Session, scheduled for Thursday, June 6, promises to be a most interesting one; it was arranged for by the Fuel Conservation Committee of the Engineering Council. A. A. Potter, Dean of the Engineering Schools, University of Kansas, will read a paper on "An Investigation of the Fuel Problem in the

(*Continued on page 762*)

Figuring Furnace-Grate Area

Various more or less confusing ideas are held by engineers and stoker manufacturers regarding the figuring of grate area. Every manufacturer has some rule based upon his experience with his particular equipment. This article sets forth the rules followed by a number of manufacturers as to what is considered active grate and as to whether actual or projected grate area is used in figuring the grate area of their stokers.

If a boiler containing 5000 sq.ft. of heating surface were to be installed, how much grate area would you put in the furnace and how would the grate area of the various types of stokers manufactured be figured? In the general run of power plants the ratio of grate area to the boiler-heating surface averages about 1 to 56. This ratio is as low as 1 to 48 and as high as 1 to 69 in individual cases. One power plant now in operation is so overstokered that the ratio is about 1 to 27. From the prevailing custom it would appear that a boiler plant is designed for so many square feet of heating surface per boiler horsepower (usually 10 sq.ft.) and that the grate area is put in, not in accordance with any standard usage, but to conform to whatever ratio the designer may favor.

However, assuming that one square foot of grate area is allowed for each 50 sq.ft. of boiler-heating surface, how is the area of the grate to be figured?

The view of one stoker manufacturer is that most of them seem to hold to some rule based upon their experience with their particular equipment, and it would seem that for any particular make of stoker whatever the manufacturer considers as grate surface should be considered as the grate area of the stoker in engineering problems. The manufacturer's rules for stoker area apply to the amount of coal that can be burned per square foot of grate surface per hour with varying conditions of draft, and these rates of burning are commonly used in proportioning a stoker for the load conditions to be met.

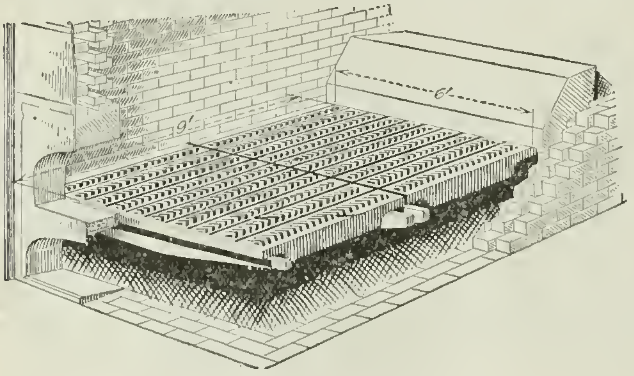

FIG. 1. ORDINARY HAND-FIRED FURNACE

Taking the double inclined type of stoker, if the manufacturer makes a practice of estimating 30 lb. of coal per square foot of projected area of the grate surface, and assuming that the data on this basis are the most reliable source of information that can be obtained, therefore on figuring up stoker sizes where the manufacturer's datum of 30 lb. of coal is used, the stoker should be rated or considered on its projected area. Under these conditions where but one stoker is considered, it appears that it makes no great difference what is considered as grate area so long as the same area is used as when computing the pounds of coal burned per square foot of grate surface per hour.

Another feature of the question of grate surface is the comparison of, say, 100 sq.ft. of, say, a single inclined gravity fuel stoker with, for instance, 100 sq.ft. of chain-grate area. There would be an extreme difference in the nature of the fuel bed of the two stokers and in the difference in air spaces, and for these reasons there cannot be any just comparison as to the performance of a square foot of grate surface per hour of one of these stokers with a square foot of the other type. One chain-grate stoker manufacturer states that under similar conditions his stoker can burn twice as much bituminous coal per square foot of area as can be burned with either a single or double inclined stoker, and this regardless of how the grate area is computed.

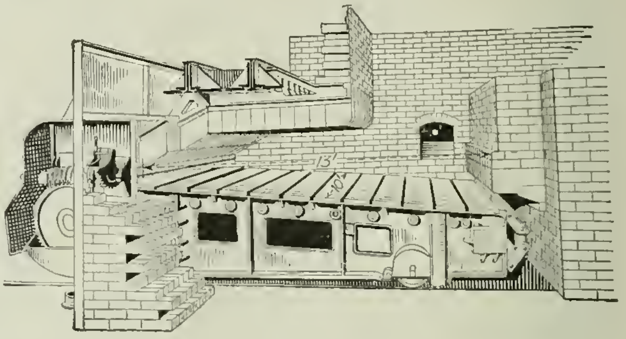

FIG. 2. INCLINED CHAIN-GRATE STOKER

This statement emphasizes what has been said—that the important thing is the performance that can be secured with a unit of grate area. This is emphasized by a consideration of the underfeed stoker which is rated on the performance of the retorts of specified dimensions.

Figuring the grate area of a chain-grate stoker is the same as calculating that for an ordinary horizontal hand-fired grate; that is, the width times the length, as shown in Fig. 1, the width of the grate being 6 ft. and the length 9 ft. The grate area would therefore be 6 × 9 = 54 sq.ft. Although the dead-plate is within the furnace walls, it is not figured as grate area.

In the case of the chain-grate stoker the normal length of the grate is figured, the normal length being the distance from the inside of the stoker feed gate to the front side of the bridge-wall or water-box when so equipped, or to the flexible bridge-wall of other design. The normal length of the grate times the width between the furnace walls at the fire line equals the grate area. Thus if the grate is 13 ft. long between the feed gate and the water-back and the width of the grate is 10 ft., the grate area would be 10 × 13 = 130 sq.ft. Some chain-grate stokers are placed level and others are on an incline, as shown in Fig. 2, the pitch being approximately ¾ in. to the foot. Thus a grate 10 ft. long would be 7.5 in. lower at the rear end than at the front. The difference in length due to the inclined grate over one set level is so small that no difference is made in calculating the area.

The type of stoker having both flat and inclined surfaces presents another phase in area calculation. Both are figured as active grate area, the actual area being considered. For instance, in Fig. 3, assume that the flat grate is 4 x 6 ft. and each of the inclined is 2 x 6 ft., then the total area of the grates would be (4 × 6) + (6 × 2 × 2) = 48 sq.ft. This method of figuring is in accordance with the assumption that active grate area, whether flat or inclined, is that part that is provided with air available for burning fuel.

Considering the front inclined type of stoker, Fig. 4. the total grate surface with the approximate dimensions is 8 x 10 ft. This is all grate surface between the front wall and the vertical portion of the bridge-wall including the dump plate. The effective grate surface includes the full width of the grate, which is 8 ft., and the distance from the top grate bar to the bottom grate bar measured on the inclined plane or the length 9 ft. or 8 × 9 = 72 sq.ft. In the type of stoker shown the area of the dump plate is not considered as effective grate surface, which is as it should be.

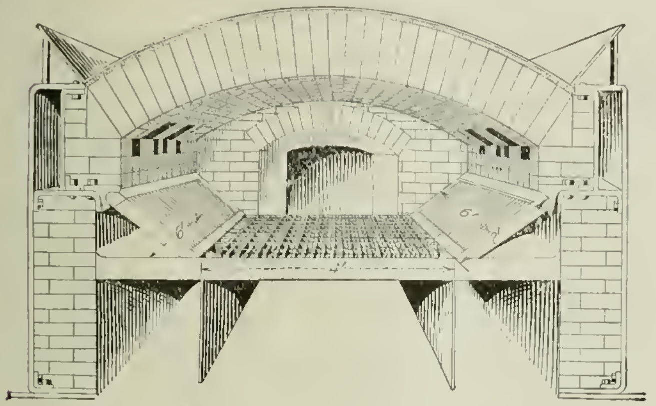

FIG. 3. COMBINED FLAT AND INCLINED GRATE

One would suppose that the method of figuring a front gravity-feed stoker would be the same as with a gravity side feed. However, the substance of what a manufacturer of the latter type says is to the effect that in stating the grate surface either the projected or the actual grate surface is specified. To figure the former the actual flat area is taken the same as with a flat grate. In figuring the actual area the length of the grate from the feed opening to the lower end of the grate is taken and this is multiplied by the depth of the furnace. This company uses one method about as frequently as the other. In drawing up specifications engineers usually specify either actual or projected area and the manufacturers specify accordingly. The actual area is approximately 25 per cent. greater in the side gravity-feed stoker than the projected area. Fig. 5 shows the type of stoker and the difference between the method of calculating the area. With the figures given the projected area would be 11.5 × 10 = 115 sq.ft. and the actual area would be 10 × 7 × 2 = 140 sq.ft., a difference of 25 sq.ft., or 22 per cent. greater actual than the projected area. The clinker-grinding portion of the stoker should not be included in the actual grate area.

In considering the underfeed stoker, Fig. 6, a difference of opinion seems to exist. One type makes use of dump plates, and these are included as projected area which is used in figuring this type of grate, as the slant of the grates at either side of the feeding trough is but slight.

A similar type of stoker does not take into consideration the grate area of the furnace as related to the coal-burning capacity. Each underfeed stoker is usually figured on the coal-burning capacity of the retort and the tuyere area, and this has nothing to do with the grate area. Furnace width, however, is taken into consideration in connection with the kind of coal burned, as if the fuel is high in refuse a greater furnace width is desired. The coal-burning capacity of an underfeed-stoker retort is dependent upon the quality of the coal and the percentage of refuse. The relation of fixed carbon and volatile matter is also important. In underfeed stokers, combustion is due to the tuyere area itself and not to any auxiliary grate area or to any combustion that may take place on any dumping plates. The underfeed principle involves the distillation of the gases at the point below the incandescent bed of fire and not on top of the grates or dump plates. Where these are resorted to increase the coal-burning capacity, the stoker system becomes a combination of underfeeding and overfeeding as the combustion on the grates and dump plates is the same as on any other system of overfeed fires.

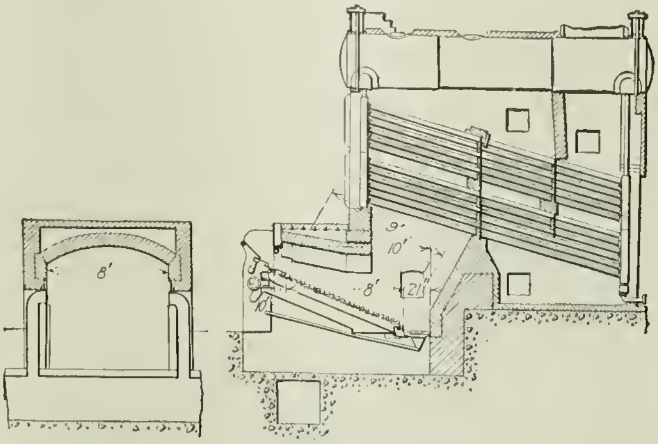

FIG. 4. FRONT GRAVITY-FEED INCLINED STOKER

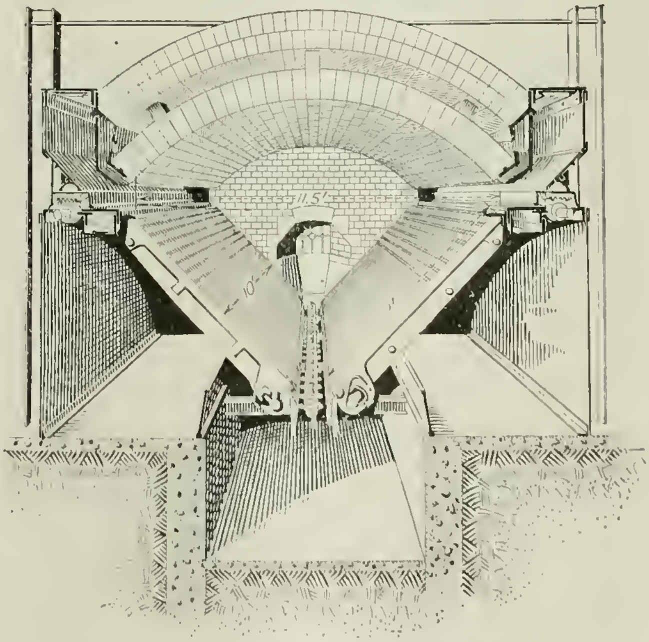

FIG. 5. SIDE GRAVITY-FEED STOKER

An inclination of the tuyere line does not affect the coal-burning capacity, and therefore there is nothing but the actual area of the air space of the tuyere to be taken into consideration. When using an underfeed stoker, any lack of furnace area due to a narrow furnace can be compensated for by securing increased room for combustion by elevating the boilers. From this it is evident that the area has nothing to do with the coal-burning capacity of an underfeed stoker.

Considering the front-feed inclined type of underfeed stoker, Fig. 7, the part of the stoker that supports the fuel and delivers air under pressure for the burning of coal should be considered as grate area; and as has already been stated, grate surface is a somewhat meaningless term and one that is misleading when used in connection with this type of stoker.

One manufacturer states that ordinarily when specifying grate area, it refers to the projected area of the stoker on a horizontal plane and includes the entire area bounded by the brick walls. Of course every portion of this area is available for the burning of some combustible. However, in his own practice for the purpose of design quite a different area is used. For instance, an imaginary line is established above the air openings which it is assumed represents the surface that is reached by the air discharged from the tuyeres and grate openings. This line establishes an imaginary active grate surface, and the projected area of this grate surface is what is termed active grate surface.

Grate surface actually means but little, as the important factor is the admission and distribution of air, and the method of determining grate area as outlined in the foregoing seems to be fairly consistent in so far as the type of stoker with which it is used goes. The imaginary surface is approximately 13 in. from the air openings and on a line with them and makes each retort of the stoker practically 13¾ sq.ft. projected area.

One builder of this type of stoker uses a double-leaf dump, of which there are two types. In one design the rear leaf of the dump is not supplied with air under pressure, and the grate area should stop at the end of the forward dump; the rear dump is not considered as grate surface. The other type has a rear dump designed to supply air under pressure from a main air duct, and since this dump can be covered with fuel, the manufacturers consider it active grate surface. Where crushing rolls are used for removing ash from the furnace, they should not be included as active grate surface.

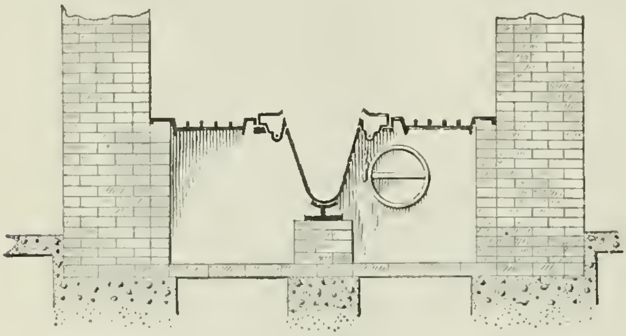

FIG. 6. ONE TYPE OF UNDERFEED STOKER

One manufacturer, when making a statement as to the grate area of the front gravity fuel underfeed stoker, always specifies whether the projected or the actual area is given because there is no standard method of determining the grate surface and the figures may be misleading unless it is specified whether actual projected area is being considered.

Another manufacturer of the last type of stoker under consideration holds views contrary to the other, as regards considering the dump plate as grate area. In this instance the usual practice in figuring the square feet of grate surface is to use the projected area of the stoker including the dump, as it is claimed that the combustion actually takes place from the front wall clear back to the bridge-wall. The reason for including the dump as grate area is because the path of least resistance for the air through the fuel bed is generally toward the bridge-wall, and even if there is no definite air supply at the rear end of the stoker, there is still ample air coming through from the fuel bed above to maintain active combustion. For this reason the makers of this stoker claim that it is legitimate to include the dump as grate area when figuring the grate surface of the underfeed stoker.

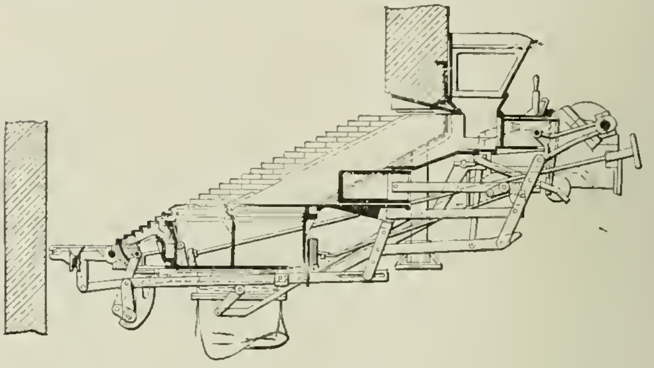

FIG. 7. FRONT-FEED INCLINED UNDERFEED STOKER

In considering the underfeed type of stoker, the volume of coal in the retort below the end of the tuyeres, the throat under the front of the plungers and the total volume of coal, which includes that in the retorts, and the thickness of the fire over the surface of the stoker, are of importance. The fuel total volume thickness averages about 1 ft., an average ranging from 18 to 24 in. at the thickest part of the fuel bed to 6 or 8 in. at the lower end and dump plate. The most satisfactory comparison of an underfeed stoker is to get the ratio between the retort volume and the total volume, or between the retort volume and the grate surface.

Boiler Capacity Depends

The active heating surface in a boiler will evaporate from 3 to 6 lb. of water from and at 212 deg. F. per square foot per hour, and 34.5 lb. of water per hour "from and at" is the standard rate of evaporation per boiler horsepower; therefore anywhere from 5½ to 12 sq.ft. of heating surface is required per boiler horsepower. This great variation in evaporative capacity is not necessarily inherent in type, design or installation. A boiler capable of the best performance may under unfavorable conditions be doing no better than the poorest. Neglect of the heating surface, inside and outside, is one of the most frequent causes of reduction in capacity.

The dollar that you contribute to the Red Cross Fund may save the life of one of our boys in France.

"Resisto" Furnace Paint and Putty

One of the certainties of boiler-room practice is that the fire-brick lining of the furnace will burn out sooner or later, depending upon the intensity of the fire. Renewing the lining is expensive, to say nothing of the loss of the boiler while the work is being done. The need for a furnace material that will withstand the high temperatures now maintained is well known, and although there has been a great advancement in the construction of such material, there still remains much to be desired.

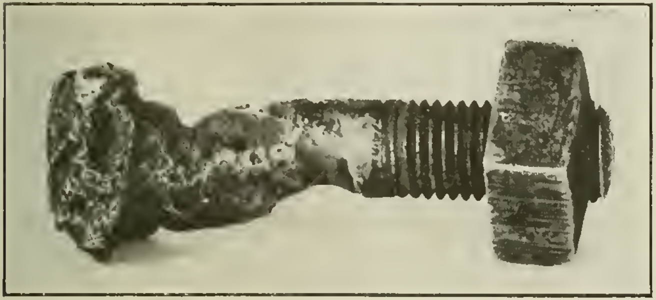

FIG. 1. PART OF BOLT NOT COVERED WITH THE PUTTY FUSED AND BURNED

Although there are several fire-resisting compounds on the market, one known as Dunbar's "Resisto," and manufactured by Wm. Clifford & Sons Co., 358 Union Ave., Elizabeth, N. J., seems to have the necessary qualifications for protecting firebrick, fire tile and iron from the effect of high temperatures. This fire-resisting compound comes in the form of a paint and a putty, and when used on furnace brick requires no drying out before starting the fires after the application.

Not only can this material be used for laying up new furnace brickwork in which ordinary fireclay is commonly used, but the putty is adaptable for pointing up old brickwork and for covering such metal as might be exposed to the furnace heat.

FIG. 2. BRICK THAT HAS BEEN PAINTED AND EXPOSED TO HIGH TEMPERATURE

In laying up new firebrick, they can be either dipped in the material or "buttered" in the usual manner. It is necessary, however, that they be clean, dry and free from grease or oil. After the work has been completed, it is coated with the paint and the furnace is then ready for use. When the brickwork is exposed to exceptionally high temperature, two coats of paint are advisable. When pointing up old brickwork the old joints must be cleaned out not less than one-half inch, given a coat of paint and then filled with enough putty to make a smooth surface.

Some idea of the heat-resisting properties of this compound and paint can be gathered from the illustrations. In Fig. 1 is shown what is left of a common wrought-iron bolt. The nut and threads were covered with a $\frac{3}{8}$-in. thickness of putty and the whole put in a blacksmith's forge and brought to a white heat. The part of the bolt not covered was fused and burned as shown. As the melting point of wrought iron is about 2550 deg. F., it shows that the bolt was subjected to a greater heat than obtains in the average boiler furnace under average conditions.

FIG. 3. BALL OF PUTTY AFTER BEING IN TEST FURNACE

The action of the paint may be seen in Fig. 2, which shows a piece of brick taken from a furnace bridgewall after four days' exposure to a temperature of about 2500 deg. F. The brick was given a coat of "Resisto" paint, which, when subjected to heat, vitrifies and forms a glazed surface, as shown by its slag-like appearance. Although the brick is in two pieces, the joints cannot be easily distinguished, thus showing that the furnace brickwork joints are protected against rapid deterioration.

Another example of the heat-resisting properties of "Resisto" is shown in Fig. 3, which is a photograph of a 2-in. diameter ball of putty that has been subjected to about 3000 deg. temperature in a test furnace. The test had to be discontinued before any effects detrimental to the putty could be noticed, as the furnace began to melt.

It would appear that where this material is used for furnace construction, it will strengthen the brickwork considerably, which, together with its heat-resisting properties, should obviate the necessity of rebuilding the furnace brickwork at such frequent intervals as has been the common practice.

Boiler Settings*

BY CHARLES H. BROMLEY

Associate Editor of "Power"

One of a number of articles on boiler settings for various stokers under the many different boilers adapted to high-volatile coals.

IT WOULD be well, at the beginning of these articles, to broadly consider boiler settings or, better, combustion volume, that one's perspective may be broadened, if need be. So much has been written on this subject that most engineers are convinced of the need of large combustion volume. But these articles are intended primarily to convince those who are not convinced, either because they are unfamiliar with the subject or because they are plainly obstinate. There are more of these people than most of us have allowed ourselves to believe there are. The secondary purpose is to present the most modern practice of setting boilers as related to improving combustion.

At least until very recently no really scientific thought was given to the relationship that should exist between combustion volume, kind of coal, combustion rate and excess air. In fact, few gave but the most superficial consideration to the subject. An example of this is illuminating: Within the month the writer asked two engineers what combustion volume per square foot of active grate surface they allowed in their boilers, volatile content of coal considered. One of these engineers is distinguished for his boiler work; the other has conspicuously contributed to power-station design and operation. The former did not know; the latter had "never looked at it that way." He sets his boilers as high as he can and lets it go at that. Obviously, this is working in the dark. Contrast this unscientific method with the elaborate research made to develop greatest efficiencies in turbine nozzles and ship propellers. Yet in the boiler the action is, for the most part, chemical and highly complex, while in both of the other cases it is mechanical. The first scientific attempt to determine the most suitable ratios of combustion

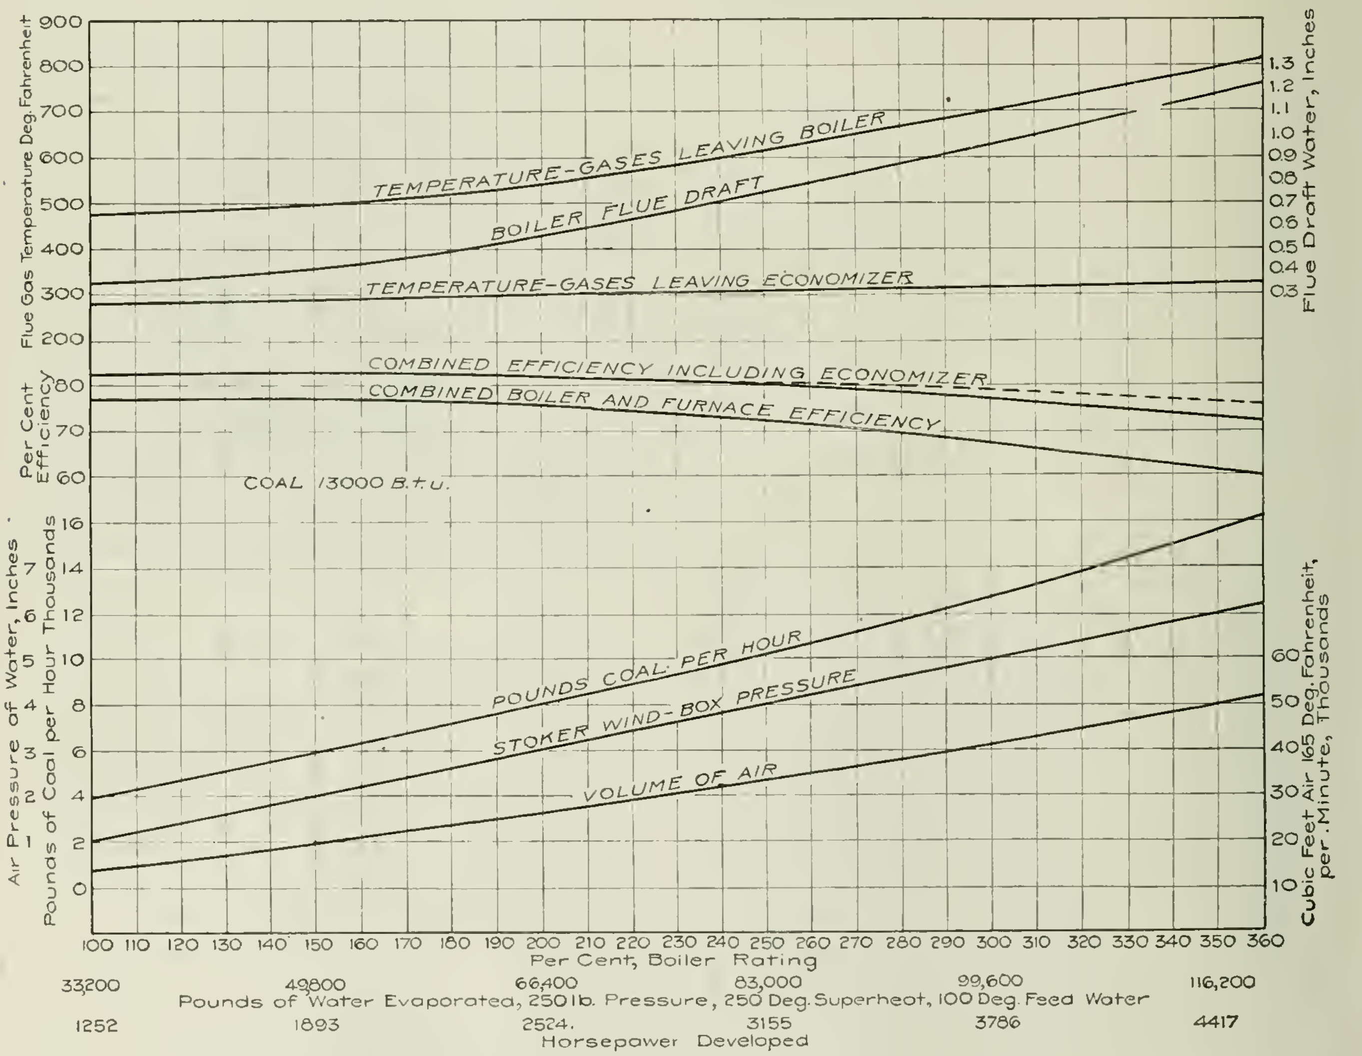

FIG. 1. PERFORMANCE CURVES, 13-RETORT UNDERFEED (WESTINGHOUSE) STOKER

---

*For previous articles of this series see the following issues of "Power": "Zone System for the Distribution of Bituminous Coal," May 14, 1918. "Coals of the United States," May 21, 1918.

volume and combustion rate for particular coals that I know of were the experiments by Kreisinger, Augustine and Ovitz for the Bureau of Mines, reported in Bulletin No. 135, recently distributed. [This bulletin was reviewed by the writer in *Power* for Apr. 23, 1918.] E. H. Peabody, in that excellent paper, "Oil Fuel," presented before the International Engineering Congress, San Francisco, September, 1915, has three interesting paragraphs on the subject of furnace volume and combustion rate, on pages 103 and 104. But as to ratios or their equivalents, he merely points out that some relation exists between the heat liberated and the combustion volume, but is not specific as to these ratios.

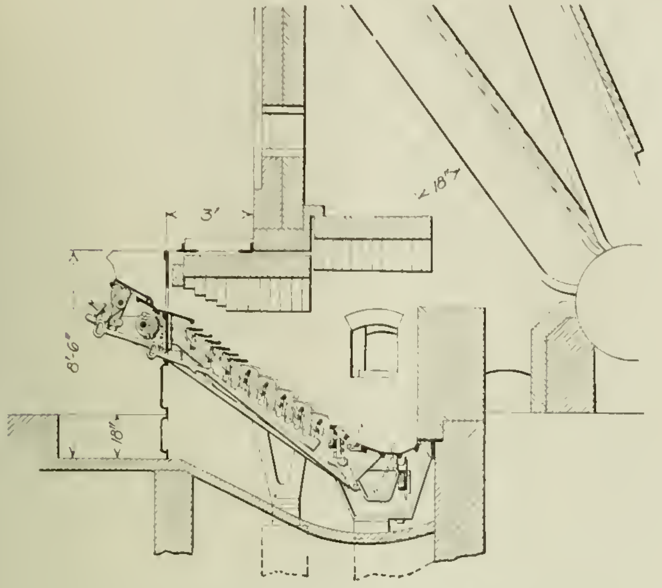

FIG. 2. SECONDARY ARCH ASSISTS IN MIXING AIR AND COMBUSTIBLE GASES

Tables I and II are from Bureau of Mines Bulletin 135; both are unusually interesting in combustion-volume studies.

TABLE I. CHEMICAL CHARACTERISTICS OF THREE COALS TESTED

	Pocahontas Coal	Pittsburgh Coal	Illinois Coal
1. Volatile matter in moisture and ash-free coal, per cent ...	18.05	34.77	46.52
2. Fixed carbon in moisture and ash-free coal, per cent	81.95	65.23	53.48
3. Carbon in moisture and ash-free coal, per cent ..	90.50	85.7	79.7
4. Volatile carbon in moisture and ash-free coal, per cent ..	8.55	20.47	26.22
5 Available hydrogen in moisture and ash-free coal, per cent .	3.96	4.70	3.96
6 Ratio of volatile carbon to available hydrogen, per cent . . .	2.16	4.35	6.[illegible]
7 Oxygen in moisture and ash-free coal, per cent .	3.32	5.59	10.93
8. Nitrogen in moisture and ash-free coal, per cent	1.19	1.73	1.70
9 Moisture accompanying 100 per cent. of moisture and ash-free coal, per cent.	2.53	2.88	22.07
10 Volatile matter times ratio of volatile carbon to available hydrogen (product of items 1 and 6)	39.00	151.00	307.00
11 Ratio of oxygen to total carbon, in moisture and ash-free coal... ..	0.0367	0.0652	0.137
12 Total moisture in furnace per lb. of coal reduced to moisture and ash-free basis, lb ..	0.409	0.501	0.70

That furnace volume alone will not necessarily give the most efficient combustion commercially is widely known. Complete mixture of air with the combustible gases is the all-important factor. This is shown by Bone's surface-combustion experiments; it is shown in the gas engine, and to a lesser degree in the underfeed stoker with its thick fuel bed. Above a limit of temperature, say 1200 to 1800 deg. F., mixture of air and combustible gases exerts a far greater influence upon the efficiency of combustion than temperature and furnace volume. In fact, furnace volume is merely an expedient to insure good mixture by lengthening the time of contact of gases and air.

If immediately above the fuel bed of an underfeed stoker there were placed a zone of high heat-resisting refractory material, broken in pieces and not so dense as to offer objectionable resistance to gas flow and protected against too rapid burning away by means of resting on water tubes integral with the boiler—in other words, using the stoker as a gas producer and passing the gas through an incandescent zone—it would likely be found that furnace volume could be materially decreased below present requirements with high-volatile coal and high combustion rates. Provision for further air admission and distribution between the fuel bed and refractory zone would of course be necessary; but it would be merely the presence of air that would be necessary, the broken refractory zone would insure good mixing because of the character of its porosity—and this zone would of course be very hot.

TABLE II. COMBUSTION SPACE REQUIRED FOR POCAHONTAS, PITTSBURGH AND ILLINOIS COALS

Completeness of Combustion, per Cent. Undeveloped Heat 1	Rate of Combustion Lb. per Sq Ft. of Grate per Hour 2	Excess of Air, per Cent 3	—Cubic Feet of Combustion Space per Sq.Ft. Grate— Pocahontas 4	Pittsburgh 5	Illinois 6

1	25	50	3.4	4.0	6.2
0.5	25	50	4.0	5.0	7.1

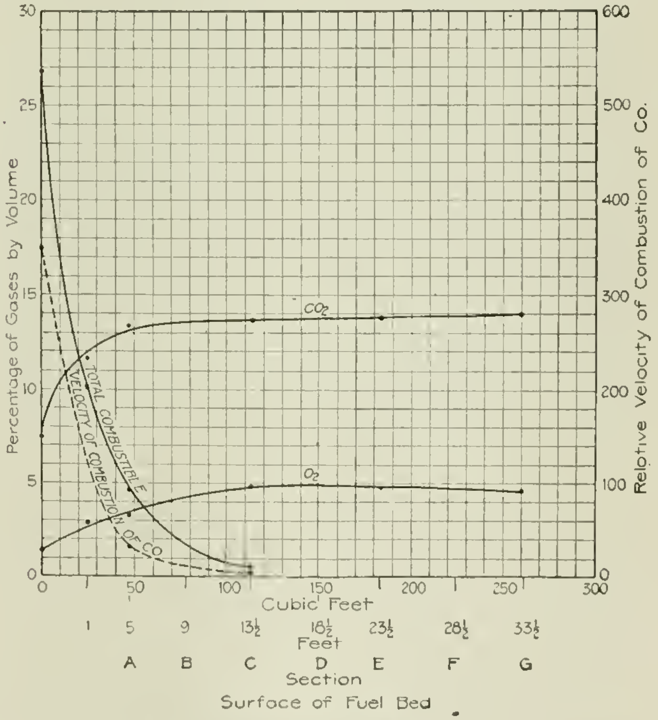

FIG. 3. NOTE INFLUENCE OF COMBUSTION VOLUME ON COMPLETENESS OF COMBUSTION

Most of us have regarded heat as the all-essential factor in combustion. Even now, unless we stop to check our thought, we regard the sole function of furnace arches as heat-radiating or reflecting surfaces.

We likely will soon universally see that except for short coking arches, the really important thing they do is to roll or scrub the gases and air and promote an intimate mixture of them *in the presence of high temperature.*

There is no question that this is the fact. Everyday boiler-room experience confirms it. Why is it that the underfeed stoker gets its efficient performance with no arches at all? Because the character of the fuel bed and air-admission areas insures a thorough mixing of air and gases within the fuel bed and in the presence of high temperature. With no arches whatever, an underfeed stoker will give an almost flat combined boiler-efficiency curve between 100 and 300 per cent. rating, and with economizers one can say, without being charitable, that it is flat. See Fig. 1.

SECONDARY ARCHES SOMETIMES SUPERFLUOUS

Secondary arches are usually at a considerable height above the fuel bed. Here they merely reflect heat and do not contribute appreciably to mixing the air and gases. They are sometimes superfluous, and when far removed from the fire in an ordinary boiler setting, are probably wholly superfluous. This is borne out by the gradual abandonment of the secondary arches on Stirling boilers of the usual class. Here the secondary arch is far from the fire and cannot exert an appreciable influence upon the fuel bed because of its distance from it, and does no good whatever in coking the coal, unless the grate is run too fast, because of the curtain wall between the coking and secondary arches.

That we too generally overlook the mixing function of arches is brought out by a statement to me by Mr. Stowe of the Laclede-Christy Clay Products Co., who, in discussing secondary arches in Stirling boilers, says that they have had no little difficulty in getting away from the secondary arch, customers insisting on their use until made thoroughly familiar with performance without them. And yet we chide marine engineers because they are slaves to precedent and custom!

A secondary arch may, however, in some settings, be useful for mixing the air and gases, provided the bridge-wall is continued high enough to form a narrow passage between the end of the bridge, wall and the end of the secondary arch, as in Fig. 2.

CHICAGO HAND-FIRED FURNACES

The excellent work of the Chicago Smoke Inspection Department under Monnett gave a memorable impetus to intelligent combustion under boilers. Though Monnett, Vial and Misostow, all of the Chicago department, did not aim to determine what ratios of furnace volumes and combustion rates were most suitable, they early found that smokelessness and economy were greatly improved by their attempts to obtain intimate mixture of air and gases in a high-temperature zone. Witness the hand-fired boiler settings developed while Monnett was chief of the Chicago Smoke Department. In all of these the chief function of the arches is that of mixing air and gases.

The curves, Fig. 3, show the effect of furnace volume upon efficiency of combustion. They are from Bureau of Mines Bulletin 135, already referred to. The stoker used was the Murphy set in a special furnace of 5 ft. square section beyond the stoker and 43 ft. 4 in. long. The coal burned was Pittsburgh screenings, and the combustion rate was 35.6 lb. coal per hour. Notice that at 13½ ft., average length of travel from the surface of the fuel bed, there is little combustible gas left. The usual boiler settings do not begin to approach the ideal as nearly as this one, and the combustion rates at peak loads are usually much higher than in these tests. In modern boiler settings for underfeed stokers, the space directly above the fuel bed is about 10 ft. wide and a mean of about 8 ft., for a 500-hp. B. & W. type boiler set with the bottom of the front header 12 ft. from the floor. The space is clear, unobstructed, with no wing walls, arches or other objects to give a rolling, mixing or scrubbing action to air and gases. It is likely that the results for the same length of gas travel at the same combustion rate would be much less favorable for this later setting than they were in the special setting used by the Bureau of Mines. It should be remembered however, that narrow gas passages without arches or wing walls conduce to gas and air stratification at too high combustion rates and high gas velocities.

The value of combustion volume is widely appreciated, however, as shown by the progress made in setting boilers high above the floor line. Eight feet was the highest a few years ago; those who had set boilers (B. & W. type) this high, went to 10 and 12 ft. on later installations. Today 12 ft. is common, and one finds 13 and 14 ft. in the very latest installations.

In the articles that are to follow, the latest and best boiler settings for the various boilers will be shown. All chief dimensions will be given. These settings are well suited to the high-volatile coals of the Middle West and, successfully burning these, they will burn any high-volatile coal obtainable on this continent. The next article will treat of settings for chain-grate stokers.

Spring Meeting of the A. S. M. E.

Middle West." In the topical discussion during this session some unusually interesting papers are expected. Other papers to be presented include: "Foundry Cost and Accounting System," by W. W. Bird; "The Public Interest as the Bedrock of Professional Practice," by Morris L. Cooke; "Moisture Reabsorption of Air-Dried Douglas Fir and Hard Pine, etc.," by Irving H. Cowdrey; "A High Speed Air and Gas Washer," by Lieut. J. L. Alden; "Investigation of the Uses of Steam in the Canning Industry," by J. C. Smallwood. On Thursday forenoon at the general session will be given the following papers: "Efficiency of Gear Drives," by C. M. Allen and F. W. Roys; "Self-Adjusting Spring-Thrust Bearing," by H. G. Reist; "Air Propulsion," by Morgan Brooks; "The Elastic Indentation of Steel Balls Under Pressure," by C. A. Briggs, W. C. Chapin and H. G. Heil; "Electric Heating of Molds," by Harold E. White; "Stresses in Machines When Starting or Stopping," by F. Hymans. Wednesday afternoon tea will be served at the Tatnuck Country Club, and on Thursday dinner will be served at the Worcester Country Club, followed by a lecture by Dr. S. I. Bailey on "Harvard's Contribution to Astronomy."

Co-operation of Public-Service and Isolated Plants

By Harold L. Alt

A rather original solution of the difficulty between the central station and the isolated plant was presented by Mr. Evans in the Apr. 23 issue of *Power*, and all credit is due him for a unique suggestion which no one else has thus far conceived. In fact, the proposition seemed so unusually good that an endeavor to check his figures was made; but here difficulties arose. To clear up the matter, I append the figures I have obtained, in the hope that Mr. Evans will point out the reasons for the discrepancies.

The heating season is usually considered as extending from Oct. 15 to Apr. 15, a period of 180 days, or, in other cases, 200 heating days. Allow 210 days for the sake of liberality, or 30 weeks. From this must be deducted 30 Sundays and the holidays of Thanksgiving, Christmas, New Year and Election Day, or 34 days in all, leaving 176 actual working days. Heating, of course, must be provided on all days.

Assuming a working day of 9 hours and a heating day of 18 hours, there must be $176 \times 9 = 1584$ hours requiring power and $210 \times 18 = 3780$ hours requiring heating, so that there will be $3780 - 1584 = 2196$ hours of heating without power. Mr. Evans, however, claims a total of 5832 hours, of which 2050 require power and 3782 require heat without power. Where does the larger amount come from?

The industrial plant assumed by him contained 1000 hp. in high-pressure boilers for heating in zero weather. This 1000 hp. apparently means developed boiler horsepower, which is roughly $1000 \times 32 = 32{,}000$ lb. of high-pressure steam produced per hour in zero weather only. At other times the amount is proportionately less, depending on the outside temperature.

Mr. Evans claims 34,000 lb., but it is not clear where he gets the larger amount, as one boiler horsepower is 33,479 B.t.u. At 150 lb. gage, with feed water at 200 deg. F., the heat required to produce 1 lb. of steam is $1195 - (200 - 32) = 1027$ B.t.u., and $33{,}479 \div 1027 = 32.6$ pounds.

As the average temperature for the heating season is 35 deg. F., or half the maximum temperature difference, the amount of steam developed for heating per year will be $3780 \times 32{,}000 \div 2 = 60{,}480{,}000$ pounds.

If the heating water from the combined converter-condenser is supplied to the buildings at 180 deg. F., with a maximum drop of 10 deg. in the transmission lines, it must leave the converter-condenser at $180 + 10 = 190$ deg. F. As it would hardly be practicable in a surface condenser to have the water approach the steam temperature within 10 deg., the maximum exhaust temperature on the coldest days will be $190 + 10 = 200$ deg. F., which corresponds to a vacuum of 6 in. of mercury. As the limit of vacuum practicable for regular work is about 28 in., it follows that the exhaust from the turbine would fluctuate between 6 in. of vacuum on the coldest days and 28 in. on the mildest days, or an average of 17 in. for the heating season.

No superheat is considered, as it is not mentioned. A large turbo-generator operates on from 15 to 18 lb. of steam per kilowatt-hour, with steam at 190 lb. gage, 125 deg. F. of superheat and a vacuum of 28 in. A decrease of 1 in. of vacuum increases the steam consumption about 3.5 per cent., and a decrease of 10 deg. of superheat increases the steam consumption 1 per cent. With 17 in. vacuum as an average, the reduction of vacuum is $28 - 17 = 11$ in., which would increase the steam consumption $11 \times 3.5 = 38.5$ per cent. The lack of superheat would increase it $125 \div 10 = 12.5$ per cent. So the total increase of steam consumption would be 51 per cent., or 1.51 times as great.

Under the conditions assumed, the minimum steam consumption would be $15 \times 1.51 = 22.65$ lb. per kw.-hr. and the maximum would be $18 \times 1.51 = 27.18$ lb. per kw.-hr., giving an average of approximately 25 lb. per kw.-hr. As the turbine must run under all sorts of fractional loads, the rate would probably be at least 30 lb. per kw.-hr., especially with steam at 150 lb. or less, instead of the 190 lb. on which the foregoing figures are based.

With a production of 60,480,000 lb. of steam in a season, it would be possible to develop $60{,}480{,}000 \div 30 = 2{,}016{,}000$ kw.-hr. As the maximum steam production on a zero day is 32,000 lb. per hour, and the turbo-generator takes about 30 lb. per kw.-hr., the size of unit required to utilize all the steam will be $32{,}000 \div 30 = 1066$ kw., or about 1000 kw., as suggested by Mr. Evans.

In the normal power plant, about 15 per cent. of the power produced is required for the operation of the plant accessories—forced draft, boiler feed, vacuum pumps, stoker engines, etc. In this case probably another 10 per cent. will be required to drive the circulating pumps for hot-water heating, which are usually of the centrifugal type and have a low efficiency.

A loss of $15 + 10 = 25$ per cent. of the total power generated would leave 75 per cent. available, or $2{,}016{,}000 \times 0.75 = 1{,}512{,}000$ kw.-hr. At Mr. Evans' figure of 1c. per kw.-hr. this would amount to $15,120 per season, as compared with his figure of $46,656. At $100 per kilowatt, the 1000-kw. plant would cost $100,000 and the interest and depreciation at 10 per cent. would be $10,000. At $0.0033 per kw.-hr. the supplies and other expenses would be 1,512,000 × $0.0033 = $4990. The total cost of running the plant would then be $14,990 a year, and the saving "to be divided as mutually agreed" would be $15,120 — $14,990 = $130 per year.

Mr. Evans has an item of $7125 which further subtracts from the value of the current produced and he explains this charge as "extra coal over heating requirements at $5 a ton." This is equivalent to charging up $7125 ÷ $5 = 1425 tons of additional coal. If (according to his figures) it takes 34,000 lb. of steam per hour in zero weather and he heats for a total period of 5832 hours, then his yearly steam consumption for heat must be $(34{,}000 \div 2) \times 5832 = 99{,}144{,}000$ lb. At 8 lb. of steam per pound of coal, this is equivalent to 12,393,000 lb. of coal, or about 6196 tons, burned to provide heat.

To run the 1000-kw. turbo-generator at full load at all times during the heating season would require approximately a steam production equal to the maximum heating requirement at all times, or just about twice the heating coal, which is 6196 tons, based on his figures. Therefore, the purpose of the additional 1425 tons is not clear, as it does not represent a sufficient quantity of coal to run the turbine on full load for 5832 hours.

Now as to the fuel consumption. All power is being purchased from the central station, where it is generated at 2 lb. of coal per kilowatt-hour, according to Mr. Evans' supposition. If the 1000-kw. machine requires 30 lb. of steam per kilowatt-hour and the evaporation is 8 lb. of steam per pound of coal, then each kilowatt-hour produced by the machine means 30 ÷ 8 = 3.75 lb. of coal. Accordingly, every hour the 1000-kw. machine is run on steam not generated for heating purposes, there is an increased fuel consumption of (3.75 — 2) ÷ 2 = 0.875, or 87.5 per cent.

This proves that the turbine in order to economize fuel consumption must be run on the steam that would otherwise be generated for heating only and must be run so as to utilize this steam alone and at such times and at such load as this quantity of steam makes it possible to carry.

The foregoing figures are not quite fair, however, as the central station uses about 2.9 lb. per kw.-hr. and probably loses 10 per cent. in transmission to the building, so that the actual figure for the central station will be 2.9 ÷ 0.90 = 3.22 lb. as compared with 3.75 for the isolated plant. The isolated plant would then be in excess of the central station by (3.75 — 3.22) ÷ 3.22 = 0.164, or 16.4 per cent.

Operation and Maintenance of Elevators—Arrangement of Cables

BY R. H. WHITEHEAD

Different schemes of roping up the winding-drum type of elevator machine, for both overhead and basement installations, are described. The limitations of these installations are also pointed out.

THE standard-elevator installations, Figs. 1 and 2, have two ropes from the winding drum to the car and two from the winding drum to the drum counterweight. Each of these pairs of ropes lead off from diametrically opposite sides of the drum, as shown at *A* and *B*, Fig. 1. *A* is the car-hoisting cables and *B* the drum-counterweight cables. The vibrating-sheave shaft and one bearing pedestal have been cut away to show the way the cables come down to the drum.

The grooving in the drum is generally arranged so that both sets of ropes use the same grooves; that is, when the car is traveling up the hoistway, the car-hoisting ropes wind on the drum and occupy the grooves that are vacated by the drum-counterweight cables, simultaneously unwinding off the drum, and vice versa for the downward travel of the car. This arrangement enables the drum to care for almost twice the rise that would be possible otherwise, since the rise of this type of elevator is limited by the amount of rope that can be wound on the drum.

For a standard installation where the elevator machine is located below, as in Fig. 1, the drum is generally continuously and spirally double-grooved in one direction and this double grooving may be either right-hand or left-hand. It is important that the angle at which the ropes lead off the drum be kept very small. This angle is denoted by *A* in Fig. 3. As shown in the figure, the angle is made minimum by locating the machine so that the cables, as they wind on and unwind off the drum, will be vertical when the car and counterweight are in mid-position in the hoistway.

When the car is at the top of the hoistway, the maximum amount of car-hoisting rope is wound on the drum, but allowance is always made on the drum for winding additional rope in case the car travels beyond the top landing. As the car descends, the hoisting ropes unwind, until finally, when the car is at the bottom of the hoistway, there remain, as a safety feature, about two complete turns on the drum to take care of any condition where the car might happen to run below the bottom landing. The drum-counterweight ropes lead off from the opposite side of the drum, as shown in Fig. 1, and are fastened to the extreme left of the drum, as at *R*.

When the car is at the top of the hoistway, the drum counterweight is at the bottom, consequently there are only a few turns of drum-counterweight rope on the drum for this position. As the car descends, the car-counterweight ropes are wound on the drum a few turns after the grooving has been vacated by the unwinding of the car-hoisting ropes. For low-rise machines, however, one half of the drum may be used exclusively for the car-hoisting ropes, and the other half for the drum-counterweight ropes.

The different methods of roping up the counterweights are also shown in Figs. 1 and 2. In Fig. 1, with the machine located in the basement, the drum-counterweight cables come down between the car-counterweight cables, pass through the center of this counterweight and are fastened to the center of the drum counterweight at *E*. For the overhead machine the drum-counterweight ropes come down, one on each side of the car-counterweight ropes, pass down through the car counterweight near its ends and are fastened to the drum counterweight at *E* and *E*.

In Fig. 7 a view is shown looking down the hoistway from above when the counterweights are located at right angles to the machine. The location of the overhead sheaves is shown and the general outline of the machine below. The length of the drum in a basement installation cannot be greater than the width of the hoistway, consequently, as the amount of rope that can be wound on the drum depends on the length of the

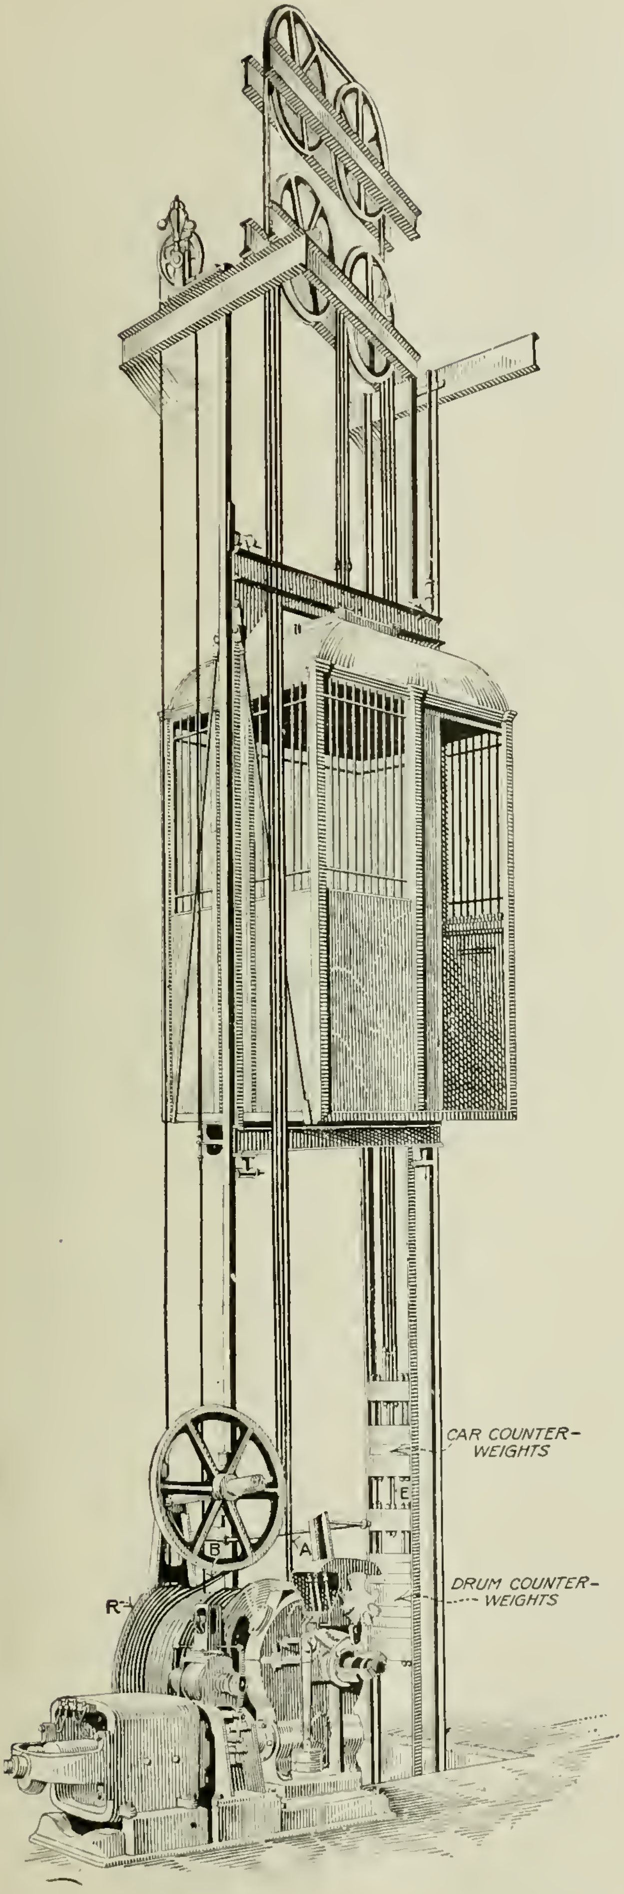

FIG. 1. BASEMENT INSTALLATION OF WINDING-DRUM TYPE ELEVATOR MACHINE

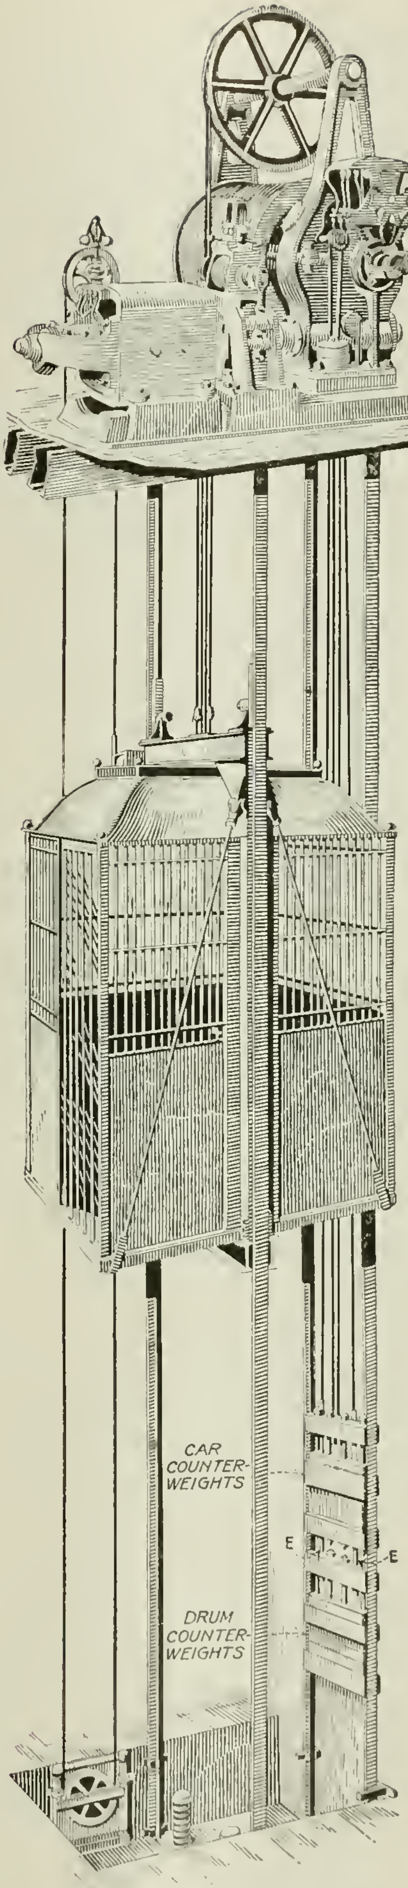

FIG. 2 OVERHEAD INSTALLATION OF WINDING-DRUM TYPE ELEVATOR MACHINE

latter, the possible rise of the car is limited by this factor. The diameter of the drum of such a machine is limited by consideration of elevator speed and space conditions.

When the elevator is overhead, as in Fig. 2, the grooving becomes a different proposition. Fig. 4 shows the rope lead when a continuously double-grooved drum machine, normally used on a lower floor or in the basement, is placed overhead. When the car is near the top of the hoistway, the length of car-hoisting ropes from the drum to the car may be only three or four feet. Therefore, for this position of the car, in order to have a good lead on the ropes, the latter must come down vertically from the drum to the car. As the car descends, the ropes lead off from the car crosshead at an increasing angle to the vertical, as at *A*. Where the distance is greater than about 35 ft., this arrangement causes an undesirable side thrust on the car, and friction between the car shoes and the guide rails.

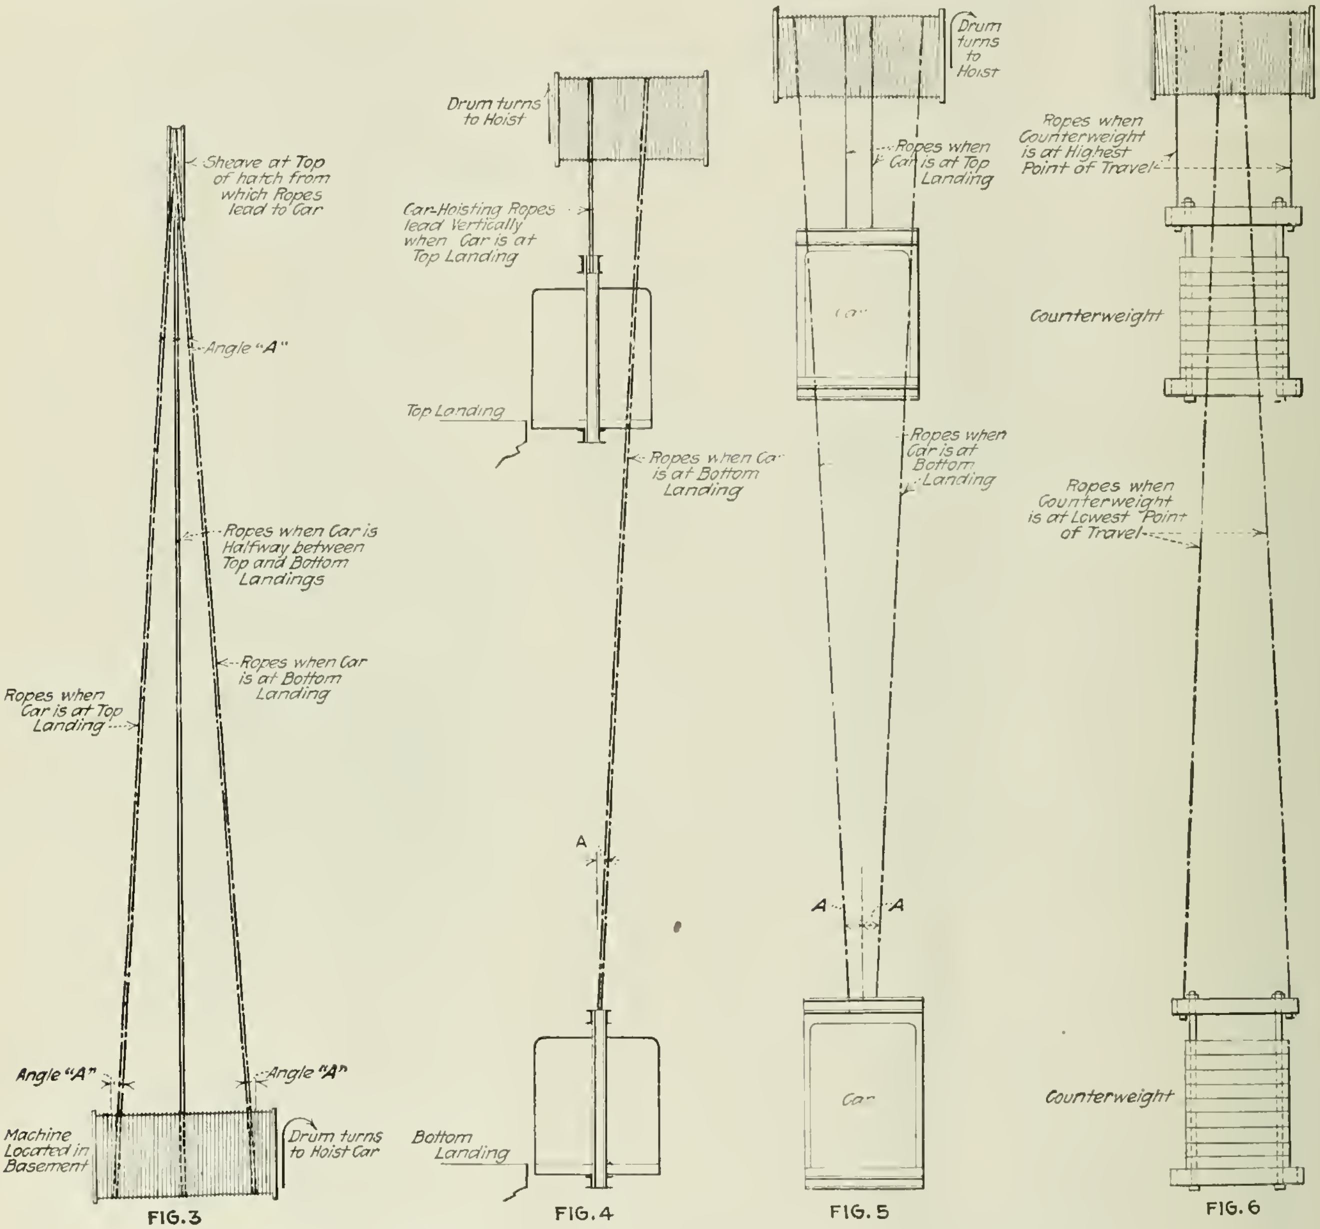

FIG. 3 FIG. 4 FIG. 5 FIG. 6

FIGS. 3 TO 6. DIFFERENT ARRANGEMENTS OF CABLES FOR ELEVATOR MACHINES

To avoid this disadvantage for high rises, a single spiral groove is used on the drum. One half of the drum is spirally grooved right-hand and the other left-hand, as shown in Fig. 5. With this arrangement the side thrust on the car caused by one of the ropes is offset by that of the other. In Fig. 5, when the car is at the top of the hoistway, the lead of the hoisting rope must be as shown—that is, from a position near the center of the drum—and as the car descends, the two car-hoisting ropes travel in opposite directions along the face of the drum toward the flanges. The ropes are fastened to the opposite ends of the drum's face. This arrangement gives the best rope lead for all conditions. Both drum-counterweight ropes are fastened at the center of the drum's face.

When the car is at the top of the hoistway, there are three or four turns of the drum-counterweight rope wound on each set of grooving between the car-hoisting ropes; the latter, for this position, are fully wound up on the drum. As the car descends and the car-hoisting ropes unwind, the drum-counterweight ropes occupy the vacated grooving on the drum as it revolves. This permits of the maximum economy of drum surface, and thus with an overhead machine it is possible to have the same rise as with a machine located below.

Fig. 6 shows how the proper lead of drum-counterweight rope is maintained. The width of the counterweight is approximately the same as the length of the drum, so that when the counterweight is near the top of the hoistway, the counterweight ropes will lead vertically from the face of the drum to the counterweight, and each of the ropes is at the same time about a maximum distance from its central position along the face of the drum. The ropes are therefore attached to the counterweights at points spaced apart equal to the maximum distance they are separated on the drum, when the counterweights are at the top of the hoistway. For high rises wide counterweights are required, but for all rises the proper proportion of width to the length of the counterweight must be maintained to avoid a condition that would cause them to jam, similar to that effect which sometimes occurs on opening a bureau drawer.

With an overhead machine the drum diameter is limited by the distance from the center of the car to the center of the counterweight. This is shown in Figs. 8 and 9. If the machine does not span this distance, as in Fig 8, then a pair of detached vibrator sheaves must be used for the drum-counterweight ropes which move along a shaft parallel with the drum. If the drum does span the distance from the center of the car to the center of the counterweight, as in Fig. 9, no vibrator sheaves are needed for the drum-counterweight ropes. Such an installation is also shown in Fig. 2.

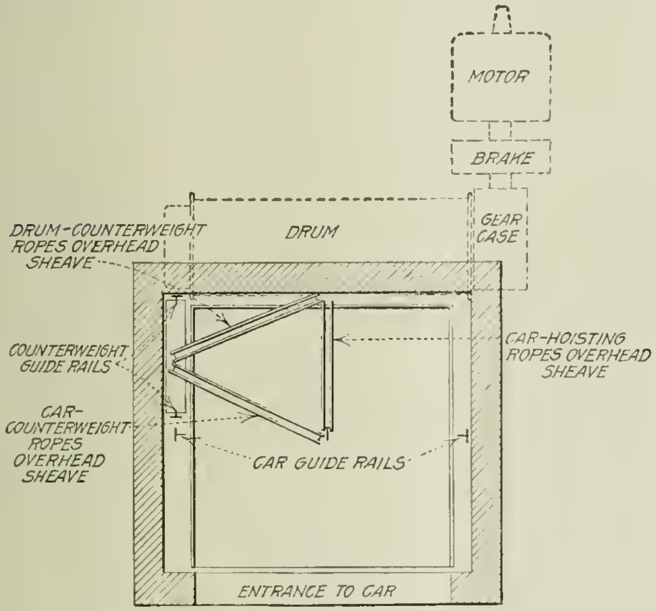

FIG. 7. LOCATION OF OVERHEAD SHEAVES WHEN MACHINE IS PLACED AT RIGHT ANGLES TO COUNTERWEIGHTS

There are some cases with machines of either the overhead or basement type, where four car-hoisting ropes are required. With a basement-type machine it is not practical to groove the drum continuously with quadruple grooving, so that the ropes can travel side by side, owing to the large pitch of grooving that would be required. Consequently, when four ropes are required with machines of either type, the machine is grooved as in Figs. 5 and 6, excepting instead of single grooves, double grooves are used, and a pair of hoisting ropes is used on each end of the drum instead of a single rope as shown. The drum-counterweight ropes are cared for in a similar manner to that shown in Fig. 6.

The winding-drum machine, as explained, has certain definite limitations and cannot on this account be used for the high rises met with in our modern high buildings. Its use is generally limited to about a 15-story building although, as explained, this depends on the particular characteristics of the installation. The next article will deal with the operation of traction-type elevator machines, which have practically no limitations as far as the length of the rise is concerned.

FIGS. 8 AND 9. LAYOUTS OF OVERHEAD MACHINES

Something About the Steam Loop

A few nights after the Saturday afternoon chat Willis had with Williams at the Stahley plant, he dropped in again, as he was on his way home for supper, to have another talk about the action of the steam loop. Williams was washing up when Willis breezed into the engine room with the remark, "I got here just in time to keep you on the job a little longer than the law demands. I guess you don't mind, do you?"

"Not so as you would notice it, seeing it's you. What's on your mind tonight?" replied Williams.

"Well, last Saturday afternoon we had a little confab about pumps, and you was cussin' 'em up hill and down and wished that some fellow would get up something that would handle hot water without any moving parts. I told you that I would give you a few pointers about the steam loop, and here I am to carry out my part of the contract."

"All right, go to it. Better take a chair and be as sociable as you can while I get into my street togs. I can listen just as well as not while I am changing."

"All right, here goes. A steam loop is a device for returning condensation from steam pipes, separators, radiators and other parts of a steam plant to a boiler, when there is not an excessive pressure between the boiler and the different parts of the system. To do that, water has to be carried from some part of the system of less pressure than is carried in the boiler and delivered to the boiler where there is a higher pressure than is carried in the piping system of the plant."

"Why the drop in pressure? If you turn steam into a pipe line, you will get the same pressure all along its length, won't you?"

"Not so as you would notice it," replied Willis. "If you don't believe it, you put a gage on the steam pipe next to your engine and you will find that there is a few pounds less pressure there than at the boiler; this is due to the length of the pipe and the number of fittings, the velocity of the steam flow and the amount of condensation that takes place. Now to get the water of condensation back to the boilers, it is generally necessary to overcome the drop in pressure and also the weight of the water or hydraulic head if you want to be technical, so to speak. The beauty of a steam loop is that it will handle water with pretty near no attention, and all of the work done by it is due to the condensation of steam in the apparatus."

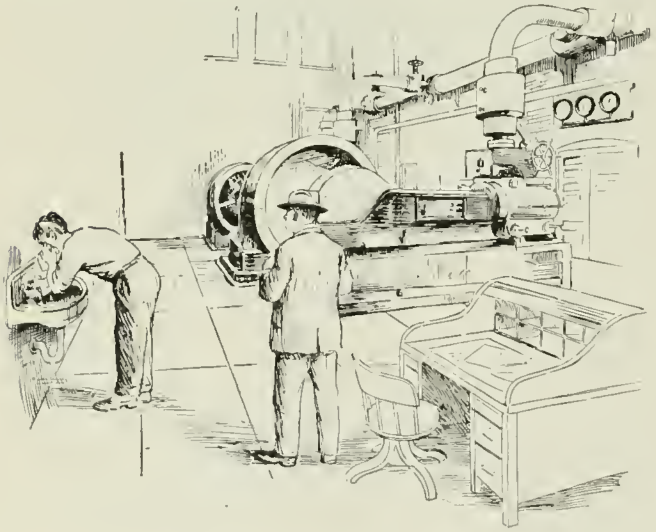

FIG. 1. "I GOT HERE JUST IN TIME TO KEEP YOU ON THE JOB A LITTLE LONGER"

"That may all be; but how is the thing made?" asked Williams.

"It is simple in construction and consists of but three parts—two vertical pipes and one horizontal. Perhaps I had better make a sketch so as to make the matter plain." (See Fig. 2.) "The pipes I will mark *A*, *B* and *C*. The vertical pipe *A* is called the drop leg, the connecting pipe *C* the horizontal and the pipe *B* the riser, the last being connected to the steam separator *D* of the engine."

"That's a funny arrangement," said Williams as he examined the sketch. "What does it do?"

"Just what I have been telling you. It will take the vapor that collects in the separator just as fast as it accumulates and return it to the boiler, and it won't allow a lot of water to collect in the separator before it begins to operate. Now to have the system work as it should, it is necessary to have the pipes proportioned right. Added to that, the vertical pipes should be covered with some insulating material, but the horizontal pipe *C* should be left bare. Under ordinary conditions the pipe *C* will act as a condenser and the loop *E* prevents the water from running back into the riser *B*."

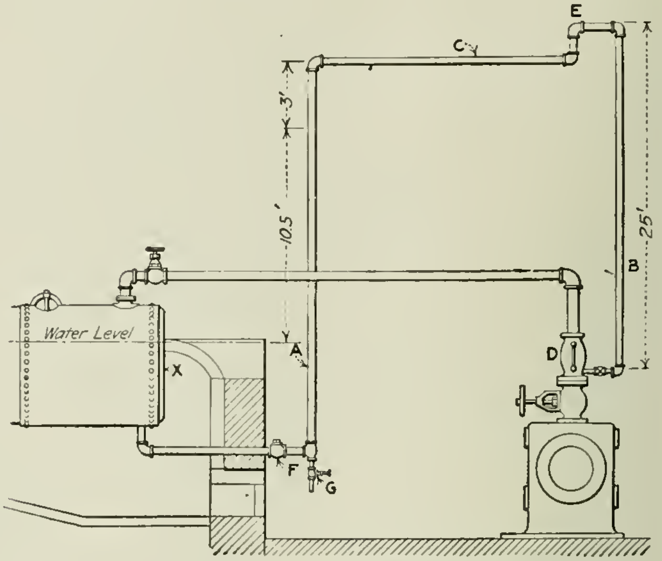

FIG. 2. LAYOUT OF A STEAM-LOOP SYSTEM

"I don't believe the thing will work," Williams exclaimed after examining the sketch once more; "that is, I don't believe it will the way you have got it drawn. Where is the steam coming from to be condensed in the horizontal pipe *C*? You haven't made any connection to the steam space of the boiler."

"Well, I declare, that was careless of me, wasn't it?" replied Willis. "Of course, if that pipe is going to act as a condenser it has got to have steam to condense and, as you say, it can't come from the boiler because there ain't no steam connection and it can't come from the blowoff connection because there is water in it up to the water level in the boiler, and a check valve prevents it from going higher. I swan, I don't see how I came to make that mistake, but perhaps there is another way for that pipe to get steam for condensing purposes," and Willis indulged in a slight grin as he continued:

"The condensation and entrained water in the separator are in the form of a moist vapor, with a low specific gravity, which rises to the condenser *C* and is turned into water. This will go on as long as there is vapor, and when the water running into the drop leg *A* reaches a height sufficient to overcome the pressure on the check valve *F*, it will run into the boiler. The weight of a cubic foot of water depends on its temperature. At 60-lb. gage pressure the temperature would be about 307 deg., using round numbers, and at, say, 110-lb. pressure it would be about 344 deg. The weight of a cubic foot of water at the corresponding temperatures would be about 57 and 56 lb., respectively. Now, a column of water 1 in. square and 1 ft. high weighs, at your pressure of 110 lb., which equals 344 deg. temperature, $56 \div 144 = 0.388$ lb. That being a fact, the height of the column of water in the pipe *A* with, say, a 4-lb. difference in pressure between the boilers and the engine would be $4 \div 0.388 = 10.3$ ft."

"All right, I will take your word for it, so go to it."

"If the water in the pipe *A* is to run into the boiler, you can see that the height of the water must be enough to overbalance the difference in pressure, as well as what friction there may be. In order to do this the pipe *A* has got to be about 30 per cent. higher than the height of the column of water that we found was necessary to balance the difference in pressure due to the drop between the boiler and the engine, or 10.3 ft. Then $10.3 \times 0.30 = 3.09$ ft., which, added to the height of the water necessary to overbalance the difference in pressure, will be $10.3 + 3.09 = 13.39$ ft., or 13.5 ft., the height of the pipe *A* above the water level in the boiler. The head of water tending to force the check valve *F* open is equal to the height of the pipe *A*, less the height necessary to balance the difference in pressure. You get this by multiplying by 0.388, the weight of a column of water 1 in. square and 1 ft. high, as we have already found. Then $13.5 - 10.3 \times 0.388 = 1.24$ lb."

"Does it make any difference where the pipe *A* enters the boiler; that is, below the water level?"

"If you will stop to think a moment, you will see that it does not. In the sketch the water enters through the blowoff pipe. It could have entered the boiler at the point, say, *X*, just as well, as it does not affect the working of the system."

"I don't see why it won't make a difference, because the column of water is higher with the lower connection than with the higher one."

"Well, well, it does look as if that were so, don't it, from the standpoint of the water in the pipe *A*? But ,on the other hand, with either a lower or higher connection, the height of the horizontal pipe *C* above the water level in the boiler will be the same, because its height is always measured from the water level in the boiler.

"Don't you see that the total difference in pressure is balanced by the height of water column in the drop leg and as the horizontal pipe is a condenser the vapor is drawn into it when it condenses and runs down into the drop leg? Then, just as soon as the column of water reaches a height sufficient to overcome the balance, the check valve opens and the water flows into the boiler, and that is about all there is to it."

"That sounds easy. I wonder that there are not more of them working in steam plants."

"Now you come to mention it, there are a lot of them operating in power plants. They take up so little room that a fellow don't see them when he goes through a plant where they are. One thing that should be remembered is to have the check valve *F* of large area, because if there is much difference in area between the top and the bottom it will prevent the check from lifting until a greater column of water has gathered in the drop leg than is necessary for its operation after the check does lift."

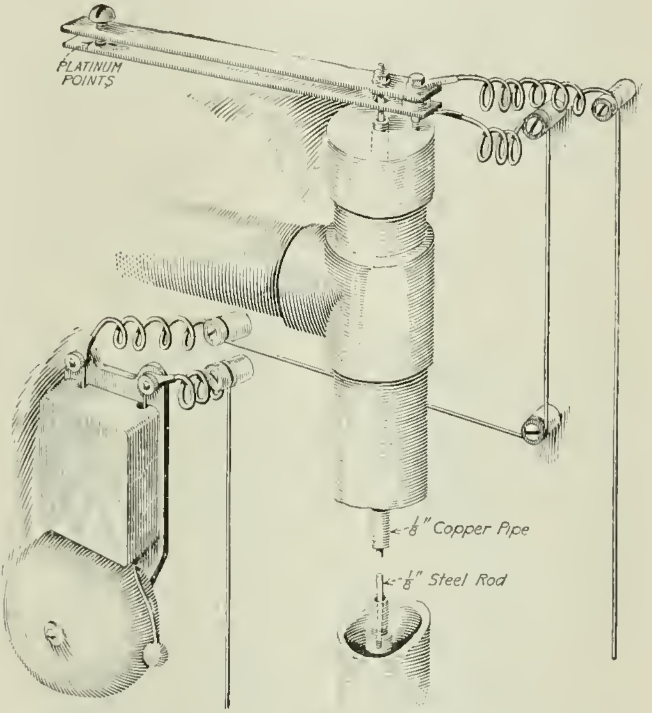
"What's the odds if it does get more water than is necessary to operate? Can't do any harm, can it?"

"The only harm that it would do would be to flood the horizontal pipe *C* and that would, of course, prevent the system from operating. Another thing that will prevent the system from operating is when it gets airbound. That is what the valve *G* is put on for so as to let the steam, water and air blow out when it is opened and so clear the system of air. Then close the valve and away the system will go as slick as a brindle pup chasing a tomcat."

High-Temperature Alarm

By Herbert B. Brand

The device shown in the illustration is for giving an alarm when the temperature of the cooling water, from the jacket of an oil engine or air compressor or the oil in the lubricating system of an engine or turbine, reaches a predetermined point. It consists of a ⅛-in. copper tube (iron-pipe size) 20 in. long, one end of which is screwed into a 1½-in. pipe cap (or other size to suit the piping used). A ⅛-in. steel rod 23 in. long is screwed into a ⅛-in. pipe cap at the lower end of the copper tube. The free end of the steel rod where it projects from the copper tube at the top is threaded for about one inch of its length. The arrangement for increasing or multiplying the motion consists of two pieces of brass ⅛ by ⅝ in. The movable member of this multiplying device carries a brass screw and locknut; the screw and lower contact preferably have platinum contact points. The action depends on the difference in the coefficient of expansion of copper and steel, so that when the copper pipe lengthens from a rise in the temperature of the fluid flowing in the large circulating pipe and the steel rod does not lengthen so much, the contacts will be brought together, closing the electric circuit and ringing the bell.



BELL CIRCUIT CLOSED BY RISE IN TEMPERATURE

Radojet Air Pump

The satisfactory performance of a condenser depends largely on how the air and the condensates are removed, as air is a nonconductor of heat and it is necessary to remove it rapidly from the condenser as the steam is condensed; if not, it will collect and form a noncondensing element around the condenser tubes and impair the heat's transfer.

With reciprocating engines operating with a vacuum of about 26 in., the reciprocating air pump performed its function, but with the adoption of the steam turbine and its high vacuum, a demand for a condenser that would maintain a high vacuum was necessary and this, of course, required a further development of the water and air pumps.

An ideal air pump would be one in which there are no moving parts, simple in construction and operation, together with a low steam consumption, combined with the additional features of minimum space and weight, no foundation, noiseless operation and no attention during operating period, quick starting, continuous service and safety of operation. Such an air pump has been developed by the C. H. Wheeler Manufacturing Co., 18th St. and Lehigh Ave., Philadelphia, Penn. It is called Radojet and is used in connection with surface, jet or barometric condensers, as well as in combination with other apparatus, wherein a vacuum has to be produced and maintained.

The principal characteristic of the Radojet air pump, Fig. 1, is the use of the steam jets for the removal of air. Although this method of removing air is not original with this pump, it has never before been developed to produce high vacuum commercially. The Radojet consists of two steam ejectors working in series, Fig. 2, the top ejector being called the first stage and the lower one the second stage.

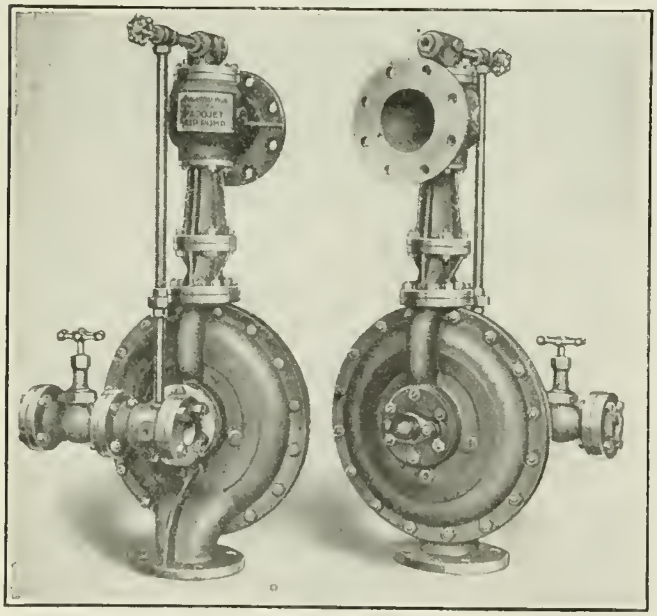


FIG. 1. TWO VIEWS OF THE RADOJET AIR PUMP

A study of Fig. 2 will show how the pump operates. Live steam at boiler pressure enters through the flanged connection *A* and strainer *B* to the expansion nozzles *C*, the path being through the pipe *D*, angle valve *E* and strainer *F*. From the expansion nozzles the steam flows across the suction chamber *G* of the first-stage ejector, which is connected to the condenser through the flanged opening *H*. As the steam expands in the nozzles *C*, it leaves them at a very high velocity, and in crossing the suction chamber *G*, it entrains the air and vapor coming from the condenser. The mixture of steam, air and vapor passes into the diffuser tube *I*, from which it is discharged at a higher absolute pressure than that of the air entering at the opening *H*, into a double annular passage *J* which communicates with the suction chambers *K* of the second-stage ejector.

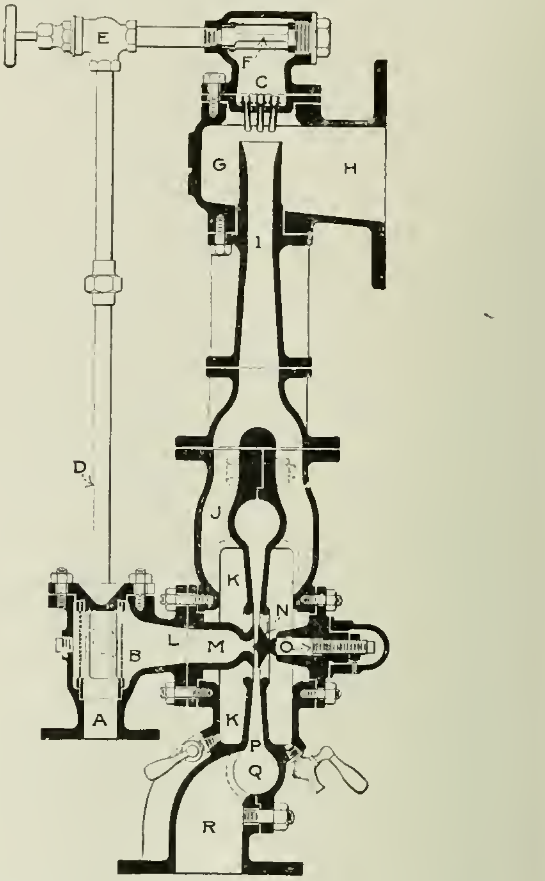

FIG. 2. SECTION THROUGH RADOJET AIR PUMP

Steam is simultaneously delivered through the strainer *B* into the passage *L*, which communicates with the annular expansion nozzle formed between the two circular disks *M* and *N*. The disk *N* can be adjusted toward or away from the disk *M* by the adjusting screw *O*. This is to vary the cross-section of the nozzle passage and thereby change the expansion ratio of the steam.

The steam from the chamber *L* is delivered radially by the annular nozzles *M* and *N* and expanding leaves it as a jet of high velocity in the form of a sheet, and in passing the suction chamber *K* entrains the air and steam coming from the first-stage nozzle and carries them into the annular diffuser *P*, thus compressing the mixture to atmospheric pressure and discharging it into the casing *Q* and out through the discharge opening *R*. The discharge from the outlet *R* may be delivered into a vented tank supplied with fresh water for boiler heating where the steam contained in the mixture is condensed.

The air frees itself from the water and escapes through the vent to the atmosphere. If an open feed-water heater is used, the discharge from the air pump is led directly to it.

In Fig. 3 is shown a surface-condenser installation fitted with Radojet air pumps arranged on a common air-suction header for removing the air. This arrangement provides for different loads and for cutting out one or more air pumps when desirable. It also prevents a total shutdown due either to an unexpected leak or a breakdown.

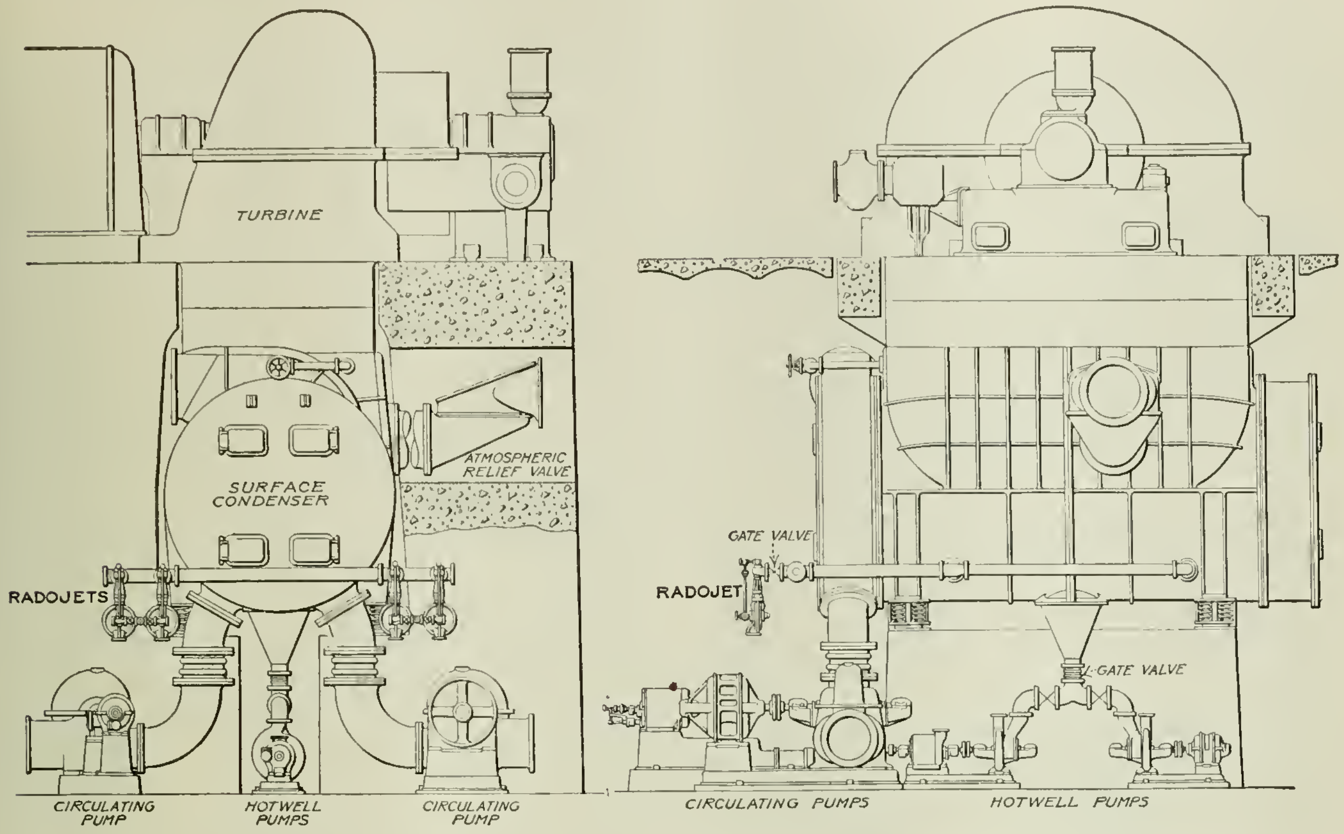

FIG. 3. END AND SIDE VIEW OF SURFACE CONDENSER EQUIPPED WITH RADOJET AIR PUMPS

This type of air pump, when used with the jet type of condenser, has the advantage of independent operation and being separated from the removal pump in that the air pump is started independently of and prior to the removal pump; and because of its ability to handle a large volume of free air even at low vacuum, it quickly creates the pressure difference necessary to lift the injection water. The action of this air pump is such that within one to three minutes from the start (depending on the size of condenser) the main injection valve can be opened, and simultaneously putting the removal pump in operation, the condenser is ready for service. This independence of the air pump makes it possible to vary the speed of the removal pump according to the variations in the discharge heads, thereby obtaining the most economical results.

Fig. 4 shows the application of this design of air pump to a low-level jet condenser. When used on large-sized condensers, two or more air pumps working in parallel are arranged. This gives the advantages mentioned in connection with surface condensers. This air pump will work with the barometric type of condenser equally as well as with those of the surface and jet types.

Owing to the absence of moving parts, this air pump does not require attention during operation, and when once adjusted and supplied with dry saturated steam of the designed pressure, it will maintain continuous service. When starting, the valve controlling the steam supply is opened and that is all there is to it.

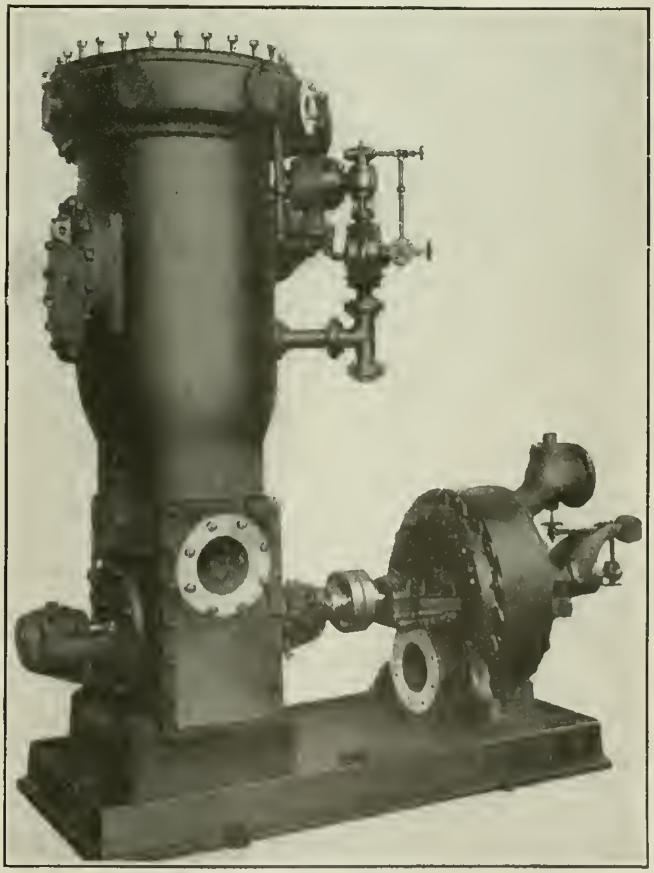

FIG. 4. RADOJET AIR PUMP ATTACHED TO A JET CONDENSER

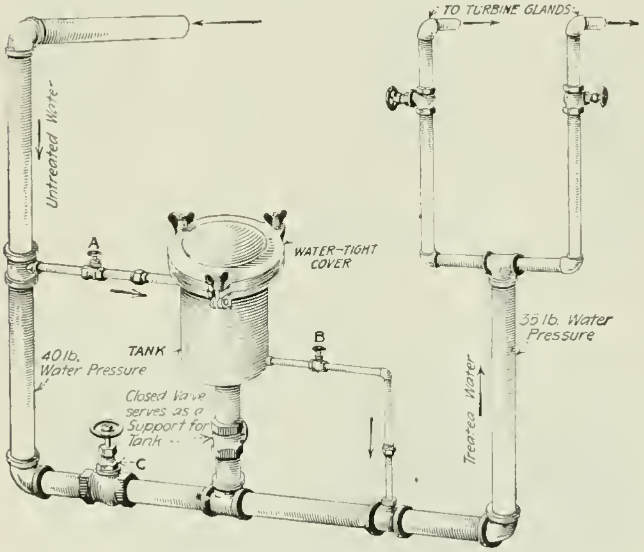
Purifying Water for Sealing Steam Turbine Glands

By J. B. Linker

In a steam-turbine installation, the glands should be sealed with soft or purified water. This is easily obtained in a plant where condensed steam is available; but in many plants such a supply is not at hand, and other means must be found to keep the glands from becoming clogged with scale. If the glands clog with scale, the runners are liable to be broken, and a kinked or unbalanced spindle may result. Many turbine owners and operators do not attach proper importance to the use of gland water that is free from impurities. The manufacturers of turbines offer arrangements for chemically treating gland water that contains impurities, and yet many customers will disregard this important matter.

The writer was called upon to start up a turbine, and on arriving at the plant found that no provision had been made for using purified or soft water on the glands. The owner wanted the turbine to be put into immediate service and ordered the machine started up by using well water that contained considerable magnesia. The writer informed the owner of the importance of using purified water, but owing to the necessity of getting the plant started, the water that contained the magnesia was used. After two weeks' operation the glands became so clogged with scale that the turbine was shut down for two days to clean the gland casings and runners. This owner doubted that two weeks' run with hard water would cause a shutdown, but it did, and he is now thoroughly convinced that it was a great risk to run. A system for using purified water was immediately installed.



WATER-SOFTENING APPARATUS FOR STEAM-TURBINE GLANDS

On starting up another plant, the same problem of a lack of purified water was encountered. It was decided that this turbine would not be started until some means was found to supply soft water for the glands. It would have required several days to construct tanks and do the necessary pipe work for installing the chemical-feeding arrangement recommended by the turbine builders. To assist the owner to get the machine going as quickly as possible and at the same time take no chance of clogging the gland casings, a temporary arrangement was rigged up to treat the gland water with chemicals. The owner was using a small tank arrangement for feeding boiler compound to the feed water. It happened that an extra tank was available, and it was piped up as shown in the figure, to feed chemicals to the gland water. It took only a few hours' work to install this tank and get the turbine in service. The result was that any desired quantity of chemical could be fed to the gland water. The chemical used was the product of the manufacturer of the tank, which is designed particularly for use in treating boiler-feed water.

In starting the turbine, the two valves *A* and *B* were opened wide and the water pressure to the glands was controlled by the valve *C*. By having the two valves *A* and *B* open, and manipulating the valve *C*, water was forced through the tank, where it dissolved the chemical. The line pressure was about 40 lb. at the valve *C* and somewhat less at the discharge side of this valve. By regulating the opening of the valves *A* and *B*, any strength of solution desired could be obtained.

It is not the intention of the writer to introduce a new arrangement for treating gland water, but it is desired to emphasize the necessity of keeping scale from forming in the gland casings and on the gland runners of turbines requiring water seals. Once the owners and operators of steam turbines are convinced of the importance of this matter, no trouble will be experienced with clogged glands.

Trials of Marine Fuels

Among the efforts to relieve the exceptional present demand upon the liquid-fuel resources of the world is an attempt to burn a colloidal mixture of Navy fuel oil and pulverized coal. Successful runs have been made with the mixed fuel off New Haven upon a vessel which has been assigned to the Submarine Defense Association for this and similar purposes.

A material is in a colloidal condition—as that term has of late been used with regard to graphite mixed with oil, etc.—when it remains suspended in the containing fluid and will not, by reason of the fineness to which it has been reduced, settle out. About 3 parts by weight of coal can be carried in this way by 7 parts of oil, giving a mixture of about the same calorific value per cubic foot as the oil itself. This mixture can be used in the same burners as the plain oil and affords a means of replacing 30 per cent. of the liquid fuel by the more abundant coal and of burning the latter smokelessly and without any complication of the apparatus.

The tests, which are being run by Haylett O'Neill, combustion engineer, of the Submarine Defense Association, will comprise trial runs to determine the practical and comparative steaming values for marine practice of the following fuels: A combination fuel consisting of a colloidal mixture of Navy fuel oil and pulverized coal; Navy fuel oil; pulverized coal with installations by various companies; pulverized coal and Navy fuel oil burned simultaneously in respective burners under the same boiler; pulverized coal and colloidal fuel burned simultaneously in respective burners under the same boiler.

Editorials

Some Benefits of the War

GIGANTIC catastrophe as it is, the world war brings in its train a few effects which may be added to the credit side of the account.

One of the smaller of these is the effect which it has had upon the mental habits of the people. We know more of geography, of peoples and their history; we pay more attention to the utterances of the leaders of the world's thought; we have a keener perception of the social and industrial problems of life. The proletariat has taken to serious reading and thinking.

The war has forced upon us a demonstration of the possibilities of thrift. We have been a nation of spendthrifts. President Wilson said in his address to the War-Savings Committee: "I suppose not many fortunate byproducts can come out of a war, but if the United States can learn something about saving out of this war, it will be worth the cost of the war; I mean the literal cost of it in money and resources. I suppose we have several times over wasted what we are now about to spend. We have not known that there was any limit to our resources; we are now finding out that there may be if we are not careful." Many a person who would have spent his all as he got it will come out of the war with a snug little sum in Savings Stamps or Liberty Bonds, and even if enforced economies have demonstrated how much one can go without and inculcated the saving habit, it will be worth something.

Closely akin to enforced economy is enforced efficiency. Shortage in materials and man-power has driven us to making better use of what we have. The carelessness in the use of coal of the old plentiful days is no longer tolerated. The possibilities of cheaper fuels are demonstrated, wastes are discovered and stopped, fuel-saving devices are sought and used, and a premium has been put upon efficiency in the power plant. Owners, engineers and firemen are alive as never before to the savings that can be made, and a standard of efficiency is being established that will set a new pace when the war is over. The same thing applies in a broad sense to all industrial operations.

To those who participate in its various activities the war will bring many advantages in an enlarged experience of the world, in contact with other people and other lands, in associations and acquaintances and friendships, in honors achieved, in an outgrown provincialism and a sense of duty done.

It will greatly improve the physical powers of millions of men. The systematic régime of the training camps, the regular routine of the cantonments, and service in the field and in the trenches will strengthen and temper the country's manhood, the fiber of which had been in danger of becoming asthenic through ease and luxury. Similarly, the widespread employment of women in the industries will result in a decrease of idle and purposeless living and an improvement in physical well-being. So there must necessarily follow a tremendous expansion of our biological capital, the benefit of which the nation will receive in the coming generation.

The war will put America on an independent basis with regard to many things for which we have been dependent upon others. It has forced us into new lines of manufacture, such as dyes, chemicals, glass for optical instruments, nitrates. It is forcing us to develop our neglected resources, as the soda deposits of Utah, the water powers, the beds of lignite and peat. It has intensified the search for oil and compelled new methods of refining its most demanded products. It has stimulated invention and research and has led to the perfecting of numerous industrial processes of permanent value.

The war revived our drooping industries and has made us the creditor nation of the world. It has made work plentiful even though it has made living dear. It has opened to us the markets of the world and compelled us to build a merchant marine to reach them and financial and commercial organizations to cultivate them. It has given us a chance to demonstrate the integrity of our purposes, the unselfishness of our motives and the beneficence of our intentions toward all mankind, has allayed the distrust of our neighbors, disarmed the enmities which were brewing against us and bound us with new ties of sympathetic friendship to our Allies. It will win us the respect of an erstwhile contemptuous assailant.

It will sound the knell of attempts at empire building by conquest, by diplomatic duplicity, by spying, intriguing, the shameless abrogation of solemn pledges, bribery, trickery and the force of arms. It may lead to the substitution of the processes of civilization for the savage arbitrament of arms in the settlement of international disputes. It may lead several paces toward the Federation of the World, when all the wealth and energy and ingenuity which nations now expend in preparing for attack or defense can be devoted to the common good of that federation.

But perhaps the greatest good that can come to this country from the war is the impetus which it has given to the concept of national efficiency. The mobilization of the industrial, the agricultural, the transportation facilities of the nation for the purposes of war will suggest their mobilization and organization and systematization and correlation for the purposes of peace. The possibilities of intelligent, systematic, scientific regulation of the food and fuel supply, of a unified system of transportation, of business conducted with a view to the greatest over-all efficiency and the common good rather than to exorbitant profit and unnecessary opportunity for gain, will be so forcibly apparent that either by the voluntary coöperation of the participants or by the forceful imposition of the common will they will be realized.

The Engineer Coming Into His Own

EVER since the beginning of the development of engineering science the engineer has been willing to work along quietly, seeking his reward only out of the joy of his accomplishments. Great as these achievements were, only recently has it occurred to the engineer and the man of science that they were entitled to greater recognition in the affairs of state. For years the legislative bodies enacted laws both wisely and unwisely without even a semblance of approval or protest from the engineers of the country.

However, times have changed and the engineering profession is coming into its own; the engineer is beginning to speak for himself. He has learned the value of coöperative effort and coördinated action on the part of engineers of all classes. As a medium of coöperation between the engineering societies, the Engineering Council was formed last June, consisting of twenty-four representatives from the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining Engineers and the United Engineering Society, to speak authoritatively for the member societies on all public questions of interest or concern to engineers.

H. W. Buck, past president of the American Institute of Electrical Engineers, said in his presidential address, June, 1917: "It is an encouraging beginning toward universal coöperation among engineers in all branches of work. In this Engineering Council we have for the first time an engineering body representing some thirty thousand engineers of sufficient scope and standing to create an engineering public opinion. Its influence is likely to be far reaching in building up the prestige of engineers in both technical and civil affairs."

That the Engineering Council is making itself felt and through it the engineer as a force in affairs of government is evidenced by the resolution adopted by this council and presented recently to the National Industrial Conference Board, that the council was opposed to certain Navy and Army bills being considered by Congress, which contained proposals detrimental to well-tried industrial methods for improving efficiency and increasing production in manufacturing plants. It is gratifying to note that after expressing the opinion, "It appears that the members of the great engineering societies of the United States are peculiarly qualified by virtue of their knowledge and experience to express an opinion upon the present efficiency of our production and the most practical means of increasing the productive capacity of both management and men and to call to public attention questionable proposals threatening our efficiency as a nation and therefore our capacity to perform our full duty in this great struggle," the National Industrial Conference Board in a resolution "respectfully requested the engineering societies of the United States to investigate and to publicly express themselves as to whether or not we are losing or gaining in industrial efficiency, and to state what causes, if any, in their opinion are influencing the condition, in what manner broadly they believe our industrial efficiency can be further stimulated."

Is not this and many other instances that have taken place during the past year only the beginning of the important part that our engineers are destined to take in our Government in the future, a part that is justly theirs by virtue of their training and qualifications, such as judgment, character, human understanding, resourcefulness, etc.?

The Opinion of An American

ANOTHER great American engineer, Dr. John J. Carty, has been awarded the Edison Medal, as reported on another page of this issue. Dr. Carty no doubt is the greatest genius in the science of telephone engineering today, having attained his high position without a college education. Although the American people may well be proud to honor him as an engineer and scientist, they should be even more proud of his thorough American spirit and his confidence in the genius of the American people. This magnificent spirit of Dr. Carty is most eloquently expressed in his address on accepting the Edison Medal, in which he says:

> We hear a great deal about the German scientist and the wonderful things he has done and has been planning. Many years ago, when German "Kultur" was interpreted by many to mean German culture, it was suggested to me that we should send to Germany to get some of the Herr doctors to teach us the high science. I always opposed that, believing that the Yankee mind, the Yankee boy, when his attention was turned to scientific problems, would surely outdistance a German. I concluded that our work could be trusted to these young Yankee minds and that they should be trained in our work and that through them we would undertake to outdistance anything that has been done in Germany. That policy has worked out successfully. The young men who have collaborated with me all these years are graduates of over one hundred universities, all here in America.
>
> When at the opening of the war there was a searching of hearts, and a census, and a taking account of stock to find out who was loyal and who was to be suspected, I know you will all be pleased to hear that among all of these scientists and all of these engineers all working in the Bell System all over the United States we were not able to find one single Hun; they were all true Americans to the core.

If this is successful in Dr. Carty's case, can it not be made so in every American industry? Have we not in the past been overlooking the great genius at home for the lesser abroad?

On May 17, Theodore M. Knappen, in an article in the daily press, said: "Tomorrow the one hundredth De Haviland 'plane equipped with a Liberty motor will be shipped to France. The De Haviland Four, with its Liberty motor installed, is the fastest flying machine in the world. It can be seen daily at the field of the Dayton (Ohio) Wright Company flying circles around the Rolls-Royce in the same sort of 'plane, and the Rolls-Royce is admittedly the most powerful aërial engine that the Old World has produced." Yes, the Yanks are coming.

Our publication of the Blackstone Roll of Honor in our issue of April 23 has got us into trouble, for it has produced an avalanche of lists from other plants. It would be impossible, of course, to reproduce all of these. One of these letters from E. C. Bingham, chief engineer of the Waldorf-Astoria, contains 134 names from his department. We wish that we could print every name, not only in this but in all of the other patriotic groups.

Correspondence

Smokelessness and Fuel Saving

On page 565 in the issue of Apr. 16 are given a number of prize-winning posters designed to encourage the abatement of smoke in Pittsburgh. The poster awarded the second prize, at the top right-hand corner of the page, and, to a lesser degree, that at the bottom right-hand corner, appear to the writer to call for a little friendly criticism. While an admirable design and "eloquently practical," the top poster might appear to give a wrong impression, yet a common one. It says "20% of Coal is lost in Smoke." But this is not quite true. The losses up the stack are about 20 per cent., sometimes more, but this is not smoke, but the total losses of heat, due either to incomplete combustion on the one hand or excess air on the other and the necessary loss chargeable to draft, and so on.

Roughly speaking, the loss due to visible smoke is perhaps between 1 and 2 per cent. in carbon and hydrocarbon particles. In addition there is the loss due to carbon monoxide or combustible gases carried away unburnt, amounting perhaps to 13 per cent. (to be added to those of actual heat carried away). These are losses due to incomplete combustion. Then there is the loss due to excess air because of air infiltration, a loss usually considered as being greater than that due to incomplete combustion and deficiency of air, because with excess air, if thoroughly mixed with the gases of combustion, the stack tends to smoke less and does not attract attention, thus leading to carelessness in firing and failure to maintain the fuel bed and apparatus in good condition.

Smoke may be due to insufficient air, insufficient furnace space, insufficient furnace temperature and insufficient intermixing of air and combustible gases. Too many plants, lacking proper settings and furnace proportions, resort to excess air as the simplest method of conforming to civic smoke ordinances, and thus smoke is reduced by resorting to excess air and inefficient combustion, increasing the invisible but decreasing the visible losses up the stack. It is well known that to obtain smokelessness without on the one hand having excess oxygen and on the other hand too little, forming carbon monoxide, is difficult. In fact, one always suspects a stack that never gives off smoke at some time as indicating an inefficient plant, where the setting and furnace proportions are favorable, but where excess air is occurring. It is also often found that higher evaporation, with some settings, can be obtained with a smoking stack than without smoke, because in such cases incomplete combustion is less wasteful than excess air. Excess air is the arch enemy of efficient combustion, because, unlike smoke, it may occur unseen and persist insidiously, instead of attracting attention.

There are too many plants attempting to overcome their smoke troubles and keep within the law by using excess air. But as a rule conservation of fuel and smoke abatement go together, since accomplishment of the former must comprise the latter, while the reverse of this is not necessarily true and unfortunately, too rarely is it true. Conservation means efficiency and smokelessness. Smoke means waste and so also may smokelessness.

I believe that many, in attempting to live up to the creed of the posters mentioned, will waste coal instead of saving it. They will attempt to prevent smoke by increasing the air supply, and while reducing smoke, will lower the efficiency of combustion and thereby waste coal. Moreover, of the 20 per cent. or more loss up the stack, that actually due to visible smoke is very small.

The writer believes he is voicing the opinions of many of *Power's* readers when he suggests that the poster awarded the second prize by the Smoke and Dust Abatement League of Pittsburgh be changed to read "20 per cent. of the Coal is lost up the Stack" instead of "20 per cent. of the Coal is lost in Smoke." The reasons for the change are twofold: First, the losses up the stack due to smoke, and even resulting from sooted boiler-heating surfaces, constitute only a small portion of the total loss; second, if a fireman bases his conclusions upon the degree of smoke emitted to indicate combustion performance, while trying to eliminate smoke by excess air, a lower efficiency will be likely to follow, although the stack does give a good indication of performance under some conditions. Smoke means fuel wasted. But for the majority of plants a smokeless stack also suggests fuel wasted. A fireman who accomplishes combustion efficiency will have little worry about smoke. It seems worth while to emphasize the difference at this time and avoid anything that tends to give a wrong impression.

Chicago, Ill. R. K. LONG.

Troubles and Their Remedies in Gas-Engine Ignition Systems

Referring to Mr. Brennan's article on "Troubles and Their Remedies in Gas-Engine Ignition Systems," Feb. 19, 1918, issue of *Power*, it is hardly fair to compare high- and low-tension ignition systems without showing where each is used at its best advantage. On motors running at high speed the high-tension system has proved itself the better, but on stationary engines of large piston displacement and low speeds, low-tension ignition is used almost exclusively.

The reason for this is that the low-tension arc gives off considerable more heat than the high-tension jump spark and therefore gives a more satisfactory ignition in the large cylinder, especially where low-grade fuels are used. On low-speed engines the mechanical make-and-break igniters give practically no trouble. On engines of large piston displacement and relatively high speeds low-tension magnetos and magnetic plugs have been used quite successfully.

Canton, China. HAROLD B. WILSON

Obstruction in Steam Separator

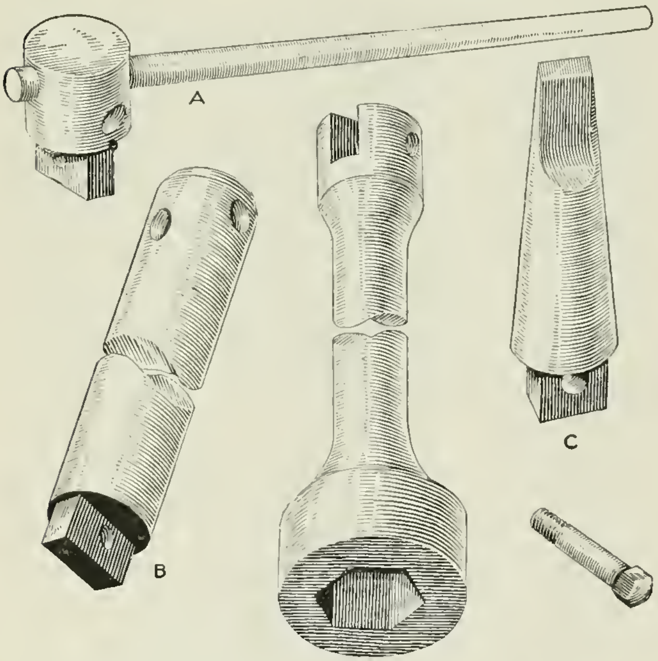
On taking charge of a power plant, I found that there was considerable drop in steam pressure between the boiler and engine at full load. Soon afterward, the cover was removed from the steam separator, and on the boiler side and partly filling the spaces were found numerous pieces of hard-rubber valve disks that had come from the 5- and 6-in. outlet valves on the boilers at different times and had been carried along the main and finally lodged in the separator. When a disk gave out on a valve, a new one would be put on, and the idea had prevailed that the missing parts of the old disk had been reduced to small particles and found their way out of the main. When the separator was cleared, the engines operated at full load without undue drop in steam pressure. This is the first time a case of this kind has come to my notice, and it may be of interest to others. JOHN JAMES.

Kingston, Ont., Canada.

Handy Socket Wrench

The illustration shows some easily made attachments for a socket wrench that will adapt it to a wide range of work. The piece *A* is for use with a bar, *B* is an extension, and the tapered or drill shank *C* permits the wrench being used in an air drill, saving considerable time and labor where a large number of nuts such as on condenser heads are to be put on. The final tightening, of course, is to be done as usual.

Concord, N. H. C. H. WILLEY.

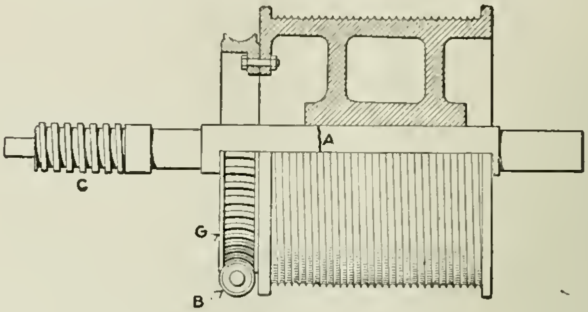


SOCKET WRENCH WITH VARIOUS ATTACHMENTS

Elevator Drum Shaft Broke

It is not an uncommon occurrence for elevators, especially the older type of machines, to drop several stories without setting the safety devices. Although they may not fall fast enough to cause any very serious damage, nevertheless they come down out of control of the operator and hit the bumpers at the bottom of the hatchway.

In the figure is shown in section the hoisting drum and gear of a belt-driven elevator machine, the car of which dropped without setting the safety devices. On inspecting the machine the only defect noticeable was, the limits did not stop the car at the top floor as they did before the accident, and on the down motion the car would stop about two feet above the basement landing. This was corrected by resetting the limit on the threaded end of the drum shaft *C*.



SECTION THROUGH DRUM, SHOWING BREAK IN SHAFT

Two hours after this accident I was called again by the mechanic, who stated that he could not get the worm of the driving shaft to mesh into the gear on the winding drum. The teeth of the gear *G* were resting on the outside edge of the thread of the worm *B*. On trying to reset the slack cable safety device, I noticed that the drum seemed to be raised up at the gear end. It was then decided to dismantle the machine and remove the drum shaft, which appeared to be either sprung or broken. When the bearing cap was removed from the gear end of the shaft, it was found that the end of the shaft could be easily moved in any direction, showing it to be broken just inside of the end of the drum, as at *A* in the figure. The machine had carried loads of 1000 to 1500 lb. with the shaft in this condition, but when sufficient weight was placed on the car the drum was lifted high enough to clear the worm. When the drum was in this position, it was rubbing on the ceiling, the friction of which acted as a brake to prevent the drum from unwinding rapidly enough to release the safety clutch on the top of the car, consequently the car went to the bottom of the hatchway before it stopped.

All elevator cars and machines should be inspected each day for any possible defects, as eternal vigilance is the price of safety. However, the foregoing is something that could not be very easily detected by an inspection. R. A. CULTRA.

Cambridge, Mass.

Sand for Extinguishing Fires

I saw a suggestion the other day that a number of buckets filled with water and some filled with sand should be placed in a convenient place in the electric station for use in case of fire. "Buckets filled with water" doesn't look good to me, as we all know what water and electricity will do, and although careful as possible, somebody is apt to get hold of the wrong bucket, especially if he comes from outside the operating room. D. R. HIBBS.

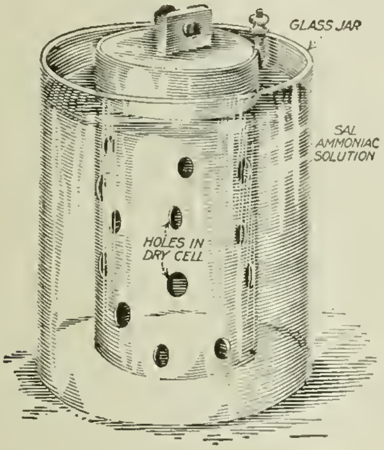
New York City.

Recharging Dry Cells

It is impossible to recharge dry-battery cells by passing an electric current through them as is done with secondary cells, because the chemical action in the cell, while in use, deteriorates and wastes the elements. Dry cells can, however, be partly recuperated by the following method, although the economy in doing this is doubtful in most cases, since new cells can be obtained more cheaply than the cost of material and time expended in recovering the old ones.

If the zinc containers of the cells are free from holes and in good condition, a sal ammoniac solution (0.25 lb. of sal ammoniac to about a quart of water) can be poured into the cell and allowed to soak into the porous compound between the carbon electrode and the zinc container, through holes bored in the asphaltum seal. When the solution has penetrated thoroughly, the cells should be resealed to prevent evaporation.

Another method, is to punch a number of holes in the zinc container and place the cell in a glass jar containing a sal ammoniac solution, using the dry cell as the carbon and zinc electrodes of the so-called wet battery, as shown in the illustration. Those who have occasion to renew their wet batteries can follow out this scheme to good advantage. Old dry cells can be obtained free of charge from most garages; then all one has to do in renewing the battery is to make a new solution and place the cell in it as stated in the foregoing. V. J. KUBANYI.

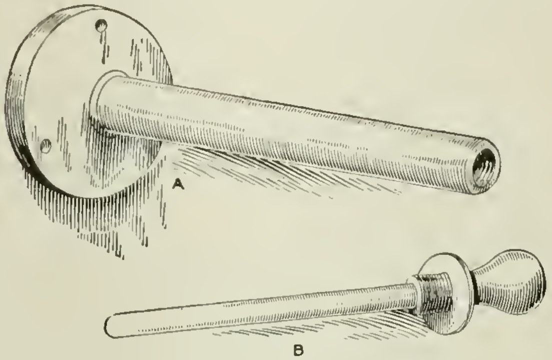


DRY CELL PLACED IN GLASS CONTAINER

New York City.

Filing Record Charts

The subject of keeping and filing recording-instrument charts is one to which considerable discussion has been devoted. The illustration shows a convenient way to file the record sheets of various curve drawing instruments so that they are always easy of access. A piece of brass pipe small enough to slip through the hole in the center of the chart is threaded into a flange as shown and mounted on the wall, as at *A*. The outer end of the pipe is threaded on the inside to receive the movable part *B*, which is made of a small rod threaded into a bushing that can be screwed into the tapped end of the pipe. On the other end of the bushing is threaded a knob and collar. The charts can be placed on the pipe and the rod screwed into the end of it, the collar keeping the charts from coming off. When any particular record sheet is wanted, all that has to be done is to unscrew the rod and slide the charts to the right of the one wanted onto the rod as it is withdrawn, and then the desired chart can be removed and the others replaced. If it is desired to mark the place where the removed chart came from, a piece of blank cardboard the size of the chart can be used for that purpose. W. H. NOSTAN.

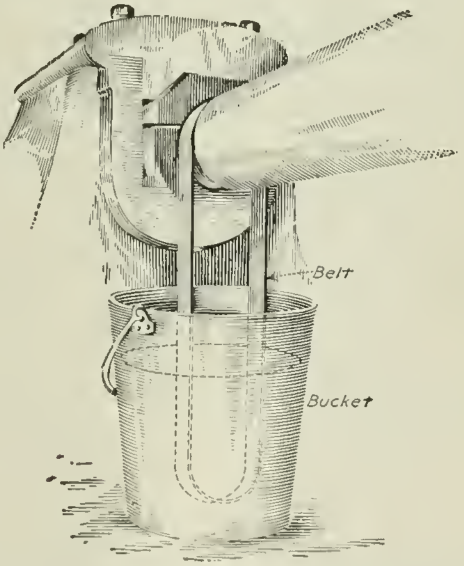


PARTS OF CHART-FILING DEVICE

Philadelphia, Penn.

Keeping Engine Bearings Cool

Some time ago a neighboring engineer had on one of his engines a bearing that ran hot no matter what ordinary measures were taken to keep it cool. As the machine could not be shut down, he tried the scheme shown in the figure with good results. A piece of old belting four or five feet long was placed around the shaft and the ends laced together. A bucket of water was then placed under the shaft and the belt allowed to hang into it. The weight of the belt on the running shaft caused it to travel through the water and carry enough of the latter to the shaft to keep the temperature near normal. Of course water worked into the bearing, but that was better than destroying it and the water did no harm until the machine could be shut down. W. T. BROWN.



ENGINE BEARING AND WATER BUCKET

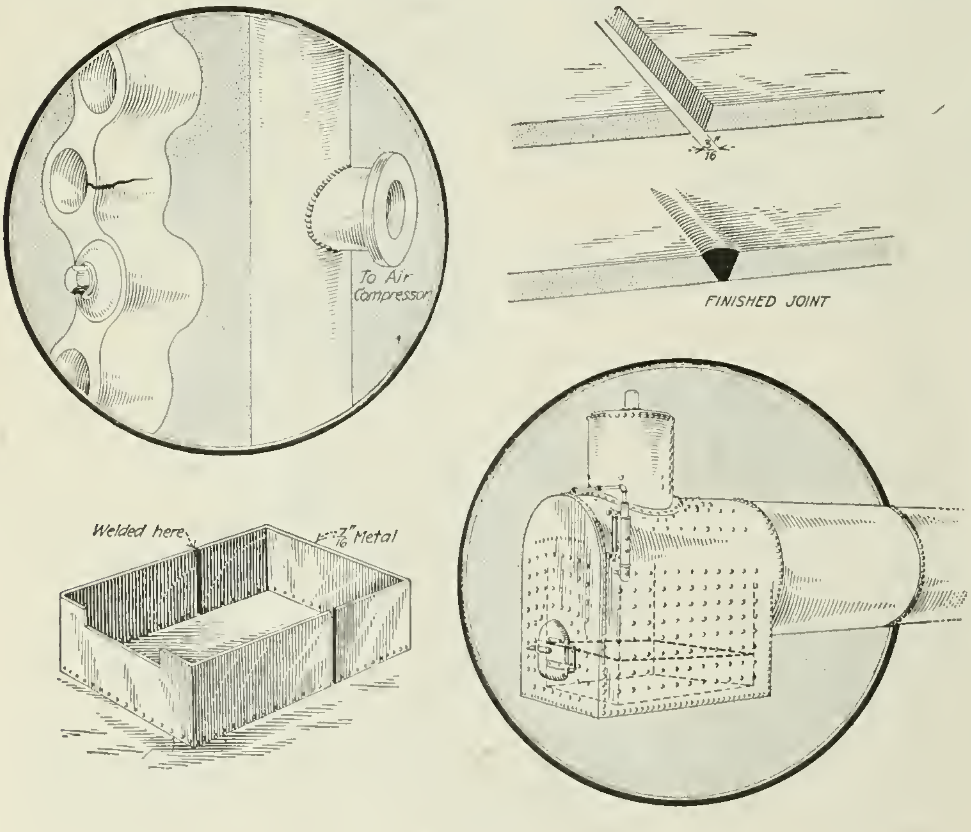
Philadelphia, Penn.

Repairs by Oxyacetylene Torch

I was interested in the way Mr. Oakley repaired the worn valve stem, as described in the issue of Feb. 12, page 230, because the same day that I received that issue I was repairing a valve stem worn in the same way, but I repaired it differently. About eight years ago I became interested in the utility of the oxyacetylene torch as part of my engine-room equipment, and it has saved me a lot of work and expense. I have done many kinds of jobs with it such as repairing broken parts of machinery and filling up worn parts, tapping steam lines, and welding cracks in steam pipes while in place.

A short time ago I put in a new air compressor that required a 4-in. steam connection, so I tapped a 5-in. pipe that was close by. I first cut a flange out of 1-in. plate with my cutting torch and welded the flange to a piece of pipe 6 in. long. Then I shut the steam off the 5-in. line and, with the torch, cut a hole in the pipe and set the 4-in. nipple into it in a straight line toward the air compressor and welded it in, doing away with a tee and two elbows. The actual welding time was an hour and a half, and a lot of labor was saved on this job. Many such jobs can be done with a welder's torch around an engine or boiler plant. About three years ago a crack developed near a handhole plate in a tube header of a B. & W. boiler, but I welded it up and have never "heard from it" since. The welding time was fifteen minutes, and the expense was trifling compared with what it would cost to take the header out and put a new one in. I would like to see brother engineers get to using the welding torch and save themselves a lot of time, labor and money. I have just finished putting in a part of a firebox in a locomotive boiler, as shown in the illustration. I have repaired three in this way, and one has been in use three years, one a year and a half and the last one about a year, and none of them has ever shown a leak although working every day. I would be pleased to see in POWER descriptions of repair jobs done by brother engineers. All that is required is practice and common sense.

Felton, Cuba. **JOHN I. CRANFORD.**



WORK THAT CAN BE DONE WITH THE OXYACETYLENE TORCH

Different Rate of Scale Formation

My attention was engaged by the letter by Thomas J. Pascoe in the issue of Apr. 9, page 521,* describing the scale conditions found in the boilers under his charge. The method of blowing soot from the tubes undoubtedly accounts for the different quantities of scale found in the tubes on the two sides of the boiler. Cleaning soot with the hand steam lance through the side doors would clean only part way across the boiler, and some of the soot blown from the tubes close to the dusting doors will be redeposited on the tubes on the far side, consequently, the rate of heat transmission is much higher on the side of the boiler near the dusting doors. With a uniform feed the amount of scale-forming material per gallon of water will be the same. If, however, on account of a difference in the amount of soot on the outside of the tubes, the rate of evaporation is two or three times as great in one tube as in another, the total amount of scale deposited will of course be greater.

After a certain amount of scale is deposited on the inside surface of the tubes near the dusting doors, the rate of heat transfer through different tubes across the width of the boiler will tend to equalize, because the greater resistance of the soot on the far tubes will be balanced by the greater resistance of the scale on the tubes nearest the dusting doors. The soot deposit accumulates more rapidly than the scale, however, and on account of the dead gas film surrounding the soot deposit, the insulating effect of the soot is much worse than that of the scale. For this reason the rate of steam-making and the amount of scale in the soot-covered tubes can never catch up to those that have been cleaned from soot.

I believe that if Mr. Pascoe will clean all the soot from each of his boiler tubes, he will find that the amount of scale deposited in each tube of one horizontal row will be very nearly the same across the full width of the boiler. The condition he has found is proof of inefficient soot removal by the hand steam lance by side dusting doors. **CHARLES DEVED.**

Inquiries of General Interest

Cross-Sectional Area of Smoke Uptake—For a horizontal return-tubular boiler should not the smoke uptake have the same areas as the united areas of the flues? T. E.

For good results from the flues as heating surfaces, the smoke area of the flues usually is made one-seventh to one-eighth the area of the grate, but with tight connections, easy courses for the smoke and good stack draft, an uptake area one-tenth of the area of the grate will be sufficient.

Operation of Blowoff Valves in Series—What is the proper manner of operating the blowoff valves on a boiler when it is equipped with two valves in series? R. M. H.

There will be more wear and cutting of the inner valve, and it will be nearly the same whether the outer valve is opened before or after the inner valve; and as the outer valve will be least injured when wide open, in blowing off it is better to first open the outer valve fully and leave it wide open until the inner valve has been fully closed.

Rerolling of Boiler Tubes—Is there any danger of running return-tubular boilers too long without rerolling the tubes provided they have never leaked? The tubes of my boilers have been used for about four years without leaking and have not been rolled during that time. W. P. S.

If the tubes have been properly flared or beaded over at the ends, rerolling them should not be done with the purpose of increasing their hold on the tube sheets as rerolling has the effect of weakening the tube material and should be performed only for the purpose of stopping leaks. To disturb the present setting of the tubes might start leaks.

Burning Wood and Coal Together—Can boiler firing be performed economically by burning wood and coal together? C. R. F.

Much better results are to be obtained, both for fuel economy and boiler capacity, by burning the different kinds of fuel separately. When wood and coal are fired alternately, or together, the light, rapidly formed ash of the wood blankets the coal and prevents a free supply of air, requiring frequent stirring of the fuel bed, which retards progressive combustion of the coal and results in waste from dropping of unburned fuel through the grates.

Composition of Ash in Coal—What does the ash in coal consist of? W. H. L.

The ash in coal may be considered to be derived from the original vegetable material or substances deposited during the laying down of the coal bed, or subsequently. The ingredients as ash exist as a mechanical mixture of silicates, oxides and sulphates; the different percentages vary greatly, usually with predominance of the silicates, and composed largely of silica (SiO_2), oxide of aluminum (Al_2O_3), oxide of iron (FeO or Fe_2O_3), oxide of lime (CaO) and oxide of sulphur (SO_2). Smaller percentages are contained of oxide of magnesium (MgO), oxide of sodium (Na_2O) and oxide of potassium (K_2O).

Adiabatic and Isothermal Expansion and Compression—What is the difference between adiabatic expansion or compression and isothermal expansion or compression? B. H.

When a gas expands and neither receives nor parts with heat during the expansion excepting the loss of heat due to the external work performed by its expansion; or when compressed it neither receives nor parts with heat during compression, excepting the mechanical equivalent of heat received for its compression, such expansion or compression is said to be adiabatic. If a gas expands and receives during expansion the exact amount of heat that it expends in performing work, or when compressed, if it rejects the amount of heat equivalent to the mechanical energy spent upon it, and there is no other heat received or lost, the temperature remains constant and the expansion or compression is called isothermal.

Injector Will Not Feed Boiler—An injector that until recently operated all right for feeding a boiler will lift but will not discharge water to the boiler. What is suggested to remedy the trouble? S. A.

The injector should be supplied with dry steam taken from a separate connection out of the top of the boiler. If any other supply is taken out of the steam connection it is likely to reduce the pressure too much. The steam-supply and water-discharge pipes, valves and fittings should be examined and cleaned of any rust or scale. If the injector will not operate with clear connections to the boiler, it should be taken apart and cleaned of scale and carefully examined. The tubes or passages may be badly worn from cutting action of the steam or from gritty water, requiring the renewal of defective parts.

Lining Up Crankshaft from Guides—Would it be practical to line up the crankshaft of an engine by taking the line from the V-guides in the frame? J. F.

For proper working conditions, the wearing surfaces of the guides should be parallel with the cylinder center line and it would be practical to line up the crankshaft from the wearing surfaces of the guides if they are known to be in proper alignment. It is better to refer all alignments to the cylinder center line, for this always is derivable from the cylinder counterbore which is not subject to wear and bears a constant relation to the framework of the engine; besides, greater accuracy in relative alignment of different parts of an engine is obtainable by referring all adjustments in as direct a manner as possible to a single permament base-line.

Loss of Heat Value from Moisture in Coal—What would be the percentage of loss of heat due to 12 per cent. moisture in coal if the dry coal contains 13,500 B.t.u. per pound? J. W. L.

The water in the coal must be evaporated from the temperature as fired and discharged as steam superheated to the temperature of the uptake gases.

The loss in B.t.u. per pound of the moist coal would be

$$W\,[212 - t + 970.4 + 0.47\,(T - 212)],$$

in which

W = Percentage of moisture;
t = Temperature of the coal as fired;
T = Temperature of the uptake gases;
0.47 = the mean specific heat of superheated steam.

Assuming $t = 60$ deg. F. and $T = 500$ deg. F., the heat loss per pound of the moist coal due to the presence of 12 per cent. moisture would be $0.12\,[212 - 60 + 970.4 + 0.47\,(500 - 212)] = 150.9$ B.t.u.

With 13,500 B.t.u. per lb. of dry coal and 12 per cent. of moisture, each pound of the moist coal would contain 88 per cent. of 13,500 = 11,880 B.t.u., so that the loss due to the presence of 12 per cent. of moisture would be

$$\frac{150.9 \times 100}{11{,}800} = 1.27 \text{ per cent. of the theoretical heat value}$$

of the moist coal. The heating value of the coal reduced to a dry coal basis would be equivalent to 11,880 — 150.9 = 11,729.1 B.t.u. per pound of the moist coal, so that the presence of 12 per cent. moisture renders the coal of

$$\frac{(13{,}500 - 11{,}729.1) \times 100}{13{,}500.} = 13.1 \text{ per cent. less commercial}$$

value than if the coal were dry.

National Coöperative Convention A. A. E.

MAY 14 at the City Club, Chicago, the American Association of Engineers held its fourth annual convention. Delegates from all engineering societies in the country had been invited jointly by the Committee of Engineering Coöperation and the association, as the question of coöperation was to receive further consideration. Representatives from approximately fifty societies attended. Practically all were local associations, or chapters of the national societies. President E. T. Perkins called the convention to order and the delegates were made welcome by John Ericson, city engineer. To conserve time the convention was split up into five special sessions as follows: No. 1, under W. D. Gerber, to review return reports of a questionnaire that had been sent out to all societies; to consider how they can avoid duplication and coördinate activities, and to report on the advisability of uniform legislation for licensing engineers. Session No. 2, headed by F. R. Low, was to review publicity given the profession due to its activities in the war. No. 3, with W. H. Finley in the chair, considered the demand for and the supply of technical men for war work and the advisability of a central coöperative employment agency to prevent the tax of commissions on engineers employed for Government work. G. W. Heald headed session No. 4, which was to consider what has been done by engineers to increase the distribution and conservation of fuel. In session No. 5 Prof. R. C. Yeoman conducted the discussion on the advisability of standardizing engineering education. Summaries of the discussions in the individual sessions were reported back to the convention at the afternoon meetings.

SESSION NO. 1 REVIEWS QUESTIONNAIRE

The questionnaire, which session No. 1 reviewed, consisted of 24 different questions divided into five distinct groups, as follows: Society activities, war programs, employment features, education and publicity. A summary of the returns from 64 societies having a total membership of 31,500 scattered throughout all parts of the country, but not including the four big national societies, may be of interest.

The number of members in active military service averaged 15 per cent., those who still desire to enter military service, 10 per cent., and the members available for emergency government work, 50 per cent. The general opinion was that the status of the engineer will be better after the war. Only two societies are at present organized so as to give systematic service in securing employment for engineers who return from the war. Other societies will be willing to do all that they can. The present demand considerably exceeds the supply of technical men in all localities except the South. The demand is primarily for engineers in positions below that of an assistant engineer. Many war industries are suffering for want of this class of men. The individual efficiency of technical men can be raised through improved education, through individual concentration, through united societies and through more active part in public life, through mixing and through earnest coöperation. Considering the increased living expenses, the sentiment of all societies is that the technical profession is paid from 50 to 75 per cent. too low; that its members are not paid sufficient for what is expected of them when compared with what other classes of men receive. The war has reduced the amount of work for engineers in private practice for all except chemical engineers. The compensation has remained about the same.

The societies generally favor licensing engineers, especially if license laws are made uniform by Federal action and if proper investigation is made so that the law provided is just. The societies are unanimously opposed to reducing the present four-year engineering courses, as even this is inadequate training. They think that the year should be 50 weeks, and the work more concentrated, so as to reduce the time element. Special short courses are also advocated for those who desire to go into war service immediately. The majority of the societies favor standardizing engineering courses, so as to obtain uniformity throughout the country, standardization to be done only in a general way and so as not to interfere with individual specialization. The societies have had only limited success in securing publicity, that obtained being in the technical press and in a few instances in the local papers. The societies that expressed an opinion recommended coördination of society activities through some national body, but as a whole there was no consensus of opinion as to what that body shall be or how coördination shall be worked out.

COÖRDINATION OF SOCIETY ACTIVITIES

Discussion at the session centered in coördination of society activities. Hunter McDonald presented the Nashville plan as an answer to question 24. It was his opinion that there were at least 200,000 engineers in the country and only about 30,000 were enrolled in the four big national engineering societies. The plan of procedure, having nine subdivisions, follows: (1) Determine what shall constitute an engineer. (2) Take a census of these in each state. (3) Perfect organizations in each state on a common constitution. (4) Determine upon an equitable representation of each state organization. (5) Arrange a central government of delegates in coöperation with the Engineering Council, delegated representatives to have a majority vote. (6) Local organizations to continue autonomous, but to become a working part of state organizations upon a basis to be worked out. (7) All local organizations in any one locality to be combined. (8) National societies to retain their organization and autonomy for technical purposes only, surrendering all other activities to the central body. (9) All other organizations intermediate between the national or central body and the membership or state organization to be disbanded.

A second plan to bring about close unity and fellowship among engineers in each community was presented by C. A. Drayer, of Cleveland. It had been prepared by the administrative committee of the Committee on Coöperation, and while professedly incomplete, owing to lack of uniformity in dues and standards of membership, it was offered as a model that might be expanded to suit conditions. Some of the organization principles in the intersociety relation problems were enumerated as follows:

Existing organizations shall be encouraged to study their own efficiency, shall be strengthened by all possible aid and no new ones created in fields already occupied.

Work shall be divided among existing organizations so there shall be no duplications or waste of effort.

Existing organizations shall be closely knit together by a workable relation capable of vigorous growth and usefulness to the profession and to the public.

Within the community unity shall be brought about as in National and state governments by each engineer belonging to the local society rather than by affiliation of local chapters or sections of the national societies with one another or with the local society. This is the essentially American ideal.

The first principle shall be the good of the whole.

JOINT MEMBERSHIPS

It was recommended that arrangements be made between any two societies that members in either society at the time the agreement is made may be admitted to the proper grade of the other society without further payment of initiation fees and without further payment of dues until the time has expired for which dues have been paid to either society, but not to exceed one year. Thereafter one initiation fee shall admit an applicant to the local society and one national society, provided he make application to both at one time and is eligible by professional qualifications; and thereafter dues in amount agreed upon by the parties to the agreement, but less than the sum of the separate dues, shall be paid to the local society, which will remit the agreed part to the national society. When any member within the jurisdiction of the local society has joined only one society after the conclusion of the arrangement and desires to take out joint membership, there shall be favorable arrangements for him to do so, but such arrangements shall be less favorable than in either of the situations mentioned.

Reference was made to the coördination that had been effected already in Ohio and Minnesota.

In a paper on the same topic presented at the afternoon session, Major Gardner S. Williams considered ideal an organization by states or districts from which members of a central council would be selected or elected and by this central council an executive board be chosen with authority to act and to direct the energies of the whole membership. This is virtually the organization of the Engineering Council, except that its authority is not clearly established. So far as a representative body for the 30,000 members of the four great national societies is concerned, the delegation of authority would meet the case, but it was questionable that it would fill the needs of the much greater number who were today outside of these national societies.

Major Williams considered it desirable to persuade the Engineering Council to provide for a general organization, to have them invite the several strong local or state societies to send delegates and with its aid to build up in every state in the Union an effective organization of the engineers therein.

It was the latter counsel that prevailed. The convention voted that a committee be appointed to confer with the Engineering Council and work out a plan satisfactory to all concerned. The discussion on licensing engineers was postponed, as there was not sufficient time to do justice to a question of so much importance. It was placed in the hands of a committee to investigate and report at the next convention.

Discussion at the Other Sessions

At session No. 2 the discussion turned to the backwardness of the engineer in public life and his undue modesty in not claiming the credit due the profession for the great engineering achievements in war and civil work. It was a defect that must be remedied if the engineering profession ever expected to take its place in the sun.

Session No. 3 brought in a resolution to the effect that the matter of fees being paid to private employment agencies for employment by the Government be brought to the attention of the proper authorities in Washington to the end that the practice be discontinued and the service be obtained from the Public Service Reserve.

A summary of the discussion at session No. 4 follows: To increase the distribution of fuel, the Fuel Administration has divided the United States into zones in order to eliminate long hauls and increase the useful service of coal cars. Industries have also been graded in order that those most essential in the conduct of the war shall have preference in order of their importance. Engineers should use and encourage others to use as far as possible coal produced nearest the point of consumption. It was also recommended that engineers wherever possible urge the prompt unloading of coal cars within twenty-four hours as ordered by the Fuel Administration. Violations of this order should be reported to the nearest local representative of the Fuel Board. Industries were urged to maintain a storage supply of at least sixty days.

To increase the conservation of fuel, engineers should become familiar with and encourage the use of bonus systems. Domestic users should be reminded to heat only such rooms as are absolutely needed, to 70 deg. or less and humidify as much as possible. Fire lightly and often, half of the fire bed at a time, when burning bituminous coal. Sift the ashes and recover the unburned coal if anthracite is burned. Watch the draft. Industrial users should be reminded that steam leaks are fuel leaks, so also are radiation losses. Both are preventable and should be reduced to a minimum. Where heating is done by steam, make the steam first do work. The power developed is a byproduct and the engine or turbine is a reducing valve. Make full use of the exhaust steam. It was the belief of the delegation that the greatest possible conservation of fuel could and should be acomplished by the carbonization of bituminous coal in byproduct coke ovens in conjunction with electric power generating plants, using the resultant coke and gas in place of coal as fuel and recovering the valuable byproducts, which are wasted when the combustion of coal takes place. Coke plants should be located at the mine where feasible.

It was suggested that all legal holidays, national or local, be observed on the nearest Monday, if said holiday should fall on any other day except Sunday. This would avoid a double stop and start each week should a holiday occur in the middle of the week.

Session No. 5 on standardizing engineering education, suggested the appointment of a committee, supplied with funds, to make up a detailed questionnaire to be sent to all societies, schools and individuals who were interested, the results to be analyzed and reported at the next convention. A resolution to this effect was laid on the table.

In the discussion following, the proposed American Academy of Engineers was subjected to severe criticism. It was considered undemocratic and not representative. Self-creation and self-perpetuation were the main objections. Before making the criticism official, a referendum, stating both sides of the question fairly, was ordered by the convention.

Realizing that the time is ripe for an inspiring code of ethics that would be a credit to the engineering profession, Isham Randolph was asked to prepare one and present it at the next convention. Other matters of importance acted upon at the afternoon session were a resolution favoring universal military training and a telegram to Director-General McAdoo to the effect that railway technical engineers did not think it just to base the wage increase on the rate of 1915. They favored the 1918 rate as a basis, and even then it would not compensate for the increase in living expenses.

The Evening Meeting

A dinner meeting in the evening was the last session of the convention. Isham Randolph, who was toastmaster, first called upon E. T. Perkins, retiring president. The work of the association during the past year was reviewed briefly. The rapid growth was gratifying. Several new chapters had been organized and every month 100 new members had been added. Service was the watchword of the association and was the secret of its success.

Samuel Insull delivered a most interesting and instructive address on Illinois War Work. Mr. Insull is chairman of the State Council of Defense of Illinois, which has made such an enviable record in organizing and carrying on the work made necessary by the war.

James A. Davis, chairman of Speakers Bureau, National War Savings Committee, spoke on the topic "Financing the War." To show the necessity of winning the war he enumerated in detail the natural resources in the conquered territory now in the possession of Germany, the great population that would be under her control and the possibilities of the future with these resources back of her. The financial status of this country was reviewed, and the great possibilities of savings were emphasized. An army of savers must stand back of the men at the front, and with their contributions this country could spend 30 to 35 billion dollars per annum for twenty years and be no poorer than today.

Alfred D. Flinn, secretary of the Engineering Council, reviewed the efforts to draw together the four large national associations and the present activities of the body he represented, its aim being "the engineering profession united to serve America."

Following, representatives from various chapters located in Indiana, Wisconsin, Minnesota, Virginia, Georgia, Pennsylvania, Texas, Oklahoma and even as far west as California, spoke briefly. All showed enthusiasm and interest in the organization, which if properly directed should result in great things for the association.

Officers for the ensuing year were announced as follows: W. H. Finley, president; H. W. Clausen, first vice president; G. F. Vivian, C. A. Gaensslen and J. T. Mullin, national auditing committee; Harold Almert, F. K. Bennett, T. M. Chapman, J. N. Hatch, Alexander Potter and J. H. Prior, directors.

When wood alcohol is to be used to any extent, have the room very well ventilated, as it affects the eyes and even produces blindness.—*Marine Engineering.*

Colonel Carty Receives Edison Medal

Dr. John J. Carty, Colonel in the United States Army Signal Corps and Chief Engineer of the American Telephone and Telegraph Company, has been awarded the Edison Medal in recognition of his meritorious achievements in the science and art of telephone engineering.

The medal was presented on Friday evening, May 17, at the annual meeting of the American Institute of Electrical Engineers in the Engineering Societies Building in West 39th St., New York. Colonel Carty is the eighth American scientist to be honored in this way, the others being Elihu Thomson, Frank J. Sprague, George Westinghouse, William Stanley, Charles F. Brush, Alexander Graham Bell and Nikola Tesla.

A statement of the history and significance of the medal was made by Dr. A. E. Kennelly, professor of electrical engineering at Harvard University and Massachusetts Institute of Technology, who was chairman of the Institute's 1917 Edison Medal Committee. Dr. Michael I. Pupin, of Columbia University, told of the work of Colonel Carty, the foremost telephone engineer in the world. The medal was delivered by the president of the Institute, E. W. Rice, Jr., also a scientist of note, who is president of the General Electric Company.

The Edison gold medal was founded in 1904 by the Edison Medal Association, an organization composed of old associates and friends of Thomas A. Edison. It is awarded annually by a committee of 24 members of the American Institute of Electrical Engineers, the first recipient being Elihu Thomson in 1909.

President Rice said in part:

> More than any other man, Colonel Carty is responsible for the development of telephone engineering as it is known today, and it is peculiarly fitting that he should receive this new honor at a time when he is working day and night to promote the best military use of mediums of communication which have been developed largely through his efforts in time of peace for the advancement of the nation's social, commercial and industrial activities.
>
> Colonel Carty is well known as the engineer of the great transcontinental telephone line, the longest in the world, and as the engineer who made possible wireless telephoning over distances up to 5000 miles.
>
> He entered the telephone business when it was in its infancy, and it would be difficult to find a phase of its development which does not bear some imprint of his genius. His technical achievements are so numerous as to prevent full recounting. He first pointed out the correct theory of induction between telephone circuits, showing how to obtain a balanced metallic circuit and devising methods for correctly transposing phantom telephone circuits. That was in 1887.
>
> In 1888 he developed the bridging bell and pointed out the importance of the bridging principle of telephone construction in obtaining efficient operation of telephone systems and in constructing balanced metallic circuits. In 1889 he invented the principle of the best and most generally used common battery system, by which a number of telephone instruments may be simultaneously operated from a single central battery. During this period he also devised important improvements pertaining to switchboard circuits having to do with the busy test feature and the connecting in of operators' instruments.
>
> In 1912 the telephone engineering force built up and directed by Colonel Carty had so far overcome the difficulties in the way of underground telephony as to make possible all-underground talking between New York and Washington, and by 1913 they had extended the range of underground telephony to connect Washington and Boston.
>
> The year 1914 witnessed the fruition of the efforts of these engineers to bring transcontinental telephony into existence, and in 1915 Colonel Carty was able to present to the world important developments in wireless telephony, which made possible the hurling of words through space across the American continent from Washington to Mare Island, California, from Washington to Hawaii, 4900 miles distant, and from Washington to Paris, bringing Europe and America into speaking distance of each other for the first time.
>
> Then came the threat of war with Germany, and in 1916 Colonel Carty coöperated with the Signal Corps of the Army and with the various departments of the Navy in making arrangements which would insure the readiness of the Bell Telephone System for military service in case this country did become involved in the great conflict. In 1917 these plans were put into active use with a marvelous degree of success.
>
> Colonel Carty's technical telephone achievements alone would entitle him to his preëminent position in his field, but he also occupies an equally high place in the regard of scientists because of the character of his work in directing, developing and coördinating telephone engineering.
>
> He has always insisted upon the importance of determining the requirements of the service before undertaking to develop specific ideas. He has always emphasized the necessity for getting the full set of facts in each case and of studying the effects of growth so that a new device may not only be satisfactory at the start, but may fit into the system as it develops. The several hundred engineers engaged by the Bell System in conducting researches, testify to the value which Colonel Carty places upon this phase of telephone work, just as they do the emphasis he puts upon the importance of keeping bad devices and methods out of the telephone plant. Colonel Carty is known also for his marked ability to make friends with and inspire confidence in those with whom he comes into contact, so that his name is one to conjure by among those for whom he works, those with whom he works and those who work for him.

Dr. Pupin said:

> Carty's life is filled with romance. He never went to college. At the age of 18 when other boys entered college he entered the service of the American Bell Telephone Co. and at the age of 25 became chief engineer of the great New York Telephone Co. He started without getting honors, titles, and now he is a doctor I do not know how many times and on the top of these titles colonel of the United States Army. If General Pershing has his way Carty will be a general before many a day. General Pershing understands that Carty is made of stuff of which great generals are made.

Colonel Carty in his speech of acceptance gave credit for the American Telephone achievements to the engineers who have been associated with him in the Bell System and paid a tribute to Maj. Gen. George O. Squier, chief signal officer of the United States Army for his work in planning before the United States entered the war for the rapid mobilization of telephone wires and telephone men for Signal Corps work. Referring to the Bell System engineers, Colonel Carty said:

> We hear a great deal about the German scientist and the wonderful things he has done and has been planning. Many years ago, when German "Kultur" was interpreted by many to mean German culture, it was suggested to me that we should send to Germany to get some of the Herr doctors to teach us the high science. I always opposed that, believing that the Yankee mind, the Yankee boy, when his attention was turned to scientific problems would surely outdistance a German. I concluded that our work could be trusted to these young Yankee minds and that they should be trained in our work and that through them we would undertake to outdistance anything that has been done in Germany. That policy has worked out successfully. The young men who have collaborated with me all these years are graduates of over one hundred universities all here in America.
>
> When at the opening of the war there was a searching of hearts and a census and a taking account of stock to find out who was loyal and who was to be suspected, I know you will all be pleased to hear that among all of these scientists and all of these engineers all working in the Bell System all over the United States we were not able to find one single Hun; they were all true Americans to the core.

Cottonseed Oil Cake as Fuel in Egypt

The high price of coal and the shortage of ocean freight space have produced a condition in Egypt under which cottonseed oil cake is being used as a substitute for coal as fuel, according to *Commerce Reports*. The high price of coal induced experiments with oil cake. The relation of the calorific value of cake to coal was found to be 1¾ tons of cake to 1 ton of north country large coal.

The present price of coal in Egypt is about $80 per ton. The price of oil cake at various times during the last two years ranging between $32.50 per ton and the present price of $15. Cake is now being largely used in place of coal in boiler plants, in hotels, restaurants, and private houses. One large concern saves two men per boiler in burning cake instead of coal. Cake ash has a value as fertilizer of about $25 per ton.

"Coal Week" from June 3 to 8

Coal week, the period from June 3 to 8, has been selected by United States Fuel Administrator Garfield for an intensive and specific drive on the early ordering of coal. The fuel organizations of the various states, the county chairmen of fuel committees throughout the nation, coal dealers, chambers of commerce, mine operators and others are all called upon to do their utmost to make this week's drive a big success.

From some states has come the objection that the trouble about the coal supply does not come from the consumers, industrial or domestic, but from the dealers, who complain that they can not get sufficient coal to deliver. In spite of this, the Fuel Administration is anxious that the early ordering campaign be vigorously pushed.

By accumulating a large volume of orders in the hands of the dealers it is expected that there will be demonstrated to every agency concerned in the distribution of coal the universality and urgency of the demand and this, in turn, will give rise to a steady and increasing pressure for rapid and equitable distribution. This is particularly true as to the railroads and other transportation agencies. Every unfilled order for coal will at once become an active and pressing argument for increased distribution efficiency. By keeping coal orders constantly accumulating, the resulting pressure, it is believed, will have the effect of maintaining production at the highest possible point during the summer months.

It is also felt that with the bulk of the year's supply of coal ordered well in advance, the various distribution agencies of the Government will be in a position equitably and properly to adjust the demands as between different communities. It will be possible accurately to gage the increased demand and properly to divide the available supply.

It is pointed out that it is obvious that the entire coal output of the country cannot all be delivered at once; but at the same time it is clear that no matter what the condition of the supply may be those orders that are on the books of the dealers will be filled prior to those received later in the year.

The state branches of the National Council of Defense are being asked to aid in this "early-ordering" drive, and the Fuel Administration believes that if the bulk of orders, both domestic and industrial, are in hand by July 1 there will result a marked improvement in railroad facilities, especially as by that time millions of dollars' worth of the new equipment ordered by the Director General of Railroads will have come into use.

While particular pains are to be taken in this campaign to reach the domestic consumer in an effort to ward off any possible coal shortage in the homes next winter, it is plain that, after all, the greatest help toward the plans of the United States Fuel Administration must come from the large industrial consumers who, by getting in early their orders for the bulk of the fuel their plants will need, can lend a tremendous impetus toward speeding up production at the mines and delivery that shall employ to the fullest all transportation facilities.

Although the "early ordering" campaign has practically only begun, its effects are already being felt in increased production. The week ending Apr. 27 showed, according to the reports of the United States Geological Survey, a total production of 11,668,000 net tons, an increase of 5.7 per cent. over the preceding week. The average production per working day was 1,946,000 net tons, compared with 1,840,000 net tons the week previous and 1,680,000 net tons during April, 1917.

The week ending Apr. 27 recorded not only the highest rate of production for the past 12 months, but was the third successive week of rising production.

There was also a gradual improvement in car service conditions in the mines during the week ending Apr. 20. Loss of production due to car shortage throughout the entire country was 16.2 per cent. as against 18.1 per cent. in the preceding week. The loss due to labor shortage was 4.8 per cent., as against 3.8 per cent. in the preceding week.

The reports showed an improvement in the demand for coal, due to the coöperation of coal consumers with the Fuel Administration's campaign for early ordering. The loss of production due to "no market" in the week ended Apr. 20 was only 1.8 per cent., for the country as a whole, as against 2.8 per cent. in the preceding week.

The loss due to "no market," however, is still large in the states west of the Mississippi River, where summer production must be maintained if the consumers are to avoid a serious coal shortage next winter. The mines in these states have ample capacity to care for the consuming territory allotted them under the zone system of distribution, but these mines must be kept at work at maximum capacity throughout the year in order to provide a proper supply.

The mines of Kansas and Missouri showed a loss of production of 7.5 per cent. due to lack of demand. Those of Oklahoma and Arkansas showed a falling off of 9.3 per cent. due to the same cause. Iowa mines lost 30.7 per cent. of their production because buyers were not available, the Pacific Coast States showed a loss of 5.8 per cent. due to this cause, and the Rocky Mountain States a loss of 12.3 per cent.

While all these figures showed an improvement as compared with previous weeks, the Fuel Administration will make a determined effort to eliminate all loss of production due to lack of market.

Richmond, Va., To Save Electric Current

The Fuel Administrator of the City of Richmond, Va., has requested the city to sell its surplus electric energy to the Virginia Railway and Power Co. If this idea is carried out, it will save a matter of 6000 tons of coal annually.

Fuel Administrator Byrd states that an investigation by electrical experts disclosed that 4,000,000 kw.-hr. of power generated by water without cost by the electric plant owned by the City of Richmond is not being utilized and is being permitted to go to waste. The commercial sale of this power is prohibited under an existing city ordinance. The sale of this surplus power to the Virginia Railway and Power Co. will enable the release of an estimated quantity of from 5000 to 6000 tons of coal annually. The City of Richmond will benefit by receiving the fair market prices of the power for which they are not now receiving any return.

Before the intercommunication is established between the municipal electric plant and the power house of the Virginia Railway and Power Co., an ordinance must be passed permitting the city to buy and sell electricity. After the passage of the ordinance the administrative board would determine whether the city desired to sell its surplus current, and whether it would sell to the Virginia Railway and Power Co., or to some other consumer. The request of the Fuel Administration is taken in certain quarters to mean the initial step toward the conservation of coal, and if such action is necessary the administration will direct that the surplus current be sold to the commercial company. There exists at the municipal plant from time to time surplus water power which, under present conditions, goes to waste. By connecting the two systems all surplus energy generated by the water power station of the city plant would be thrown into the feed main of the Virginia Railway and Power Co., and would thereby enable a corresponding reduction in fuel consumption at the steam plant of the traction company. Through this interconnection there would be added to the power supply of the city a needed surplus.

If this proposition is carried through, it will create a valuable precedent for many similar cases throughout that section of the country.

It is understood that the intercommunication between the two plants would exist only for the duration of the war, and the individuality of the power houses would in no way be disturbed. The Fuel Administration suggests that a Board of Arbitration be formed to adopt a fair rate at which the surplus electricity will be sold to the traction company, and offers to place priority orders for all equipment needed to effect the connection. It is estimated that the revenue to the city would be about $40,000 per year.

Students To Have Military Standing

To provide military instructions for the college students of the country during the present emergency, a comprehensive plan will be put into effect by the War Department, beginning with the next college year, September, 1918. The details remain to be worked out, but in general the plan will be as follows:

Military instruction under officers and noncommissioned officers of the Army will be provided in every institution of college grade which enrolls for the instruction 100 or more able-bodied students over the age of 18. The necessary military equipment will, so far as possible, be provided by the Government. There will be created a military training unit in each institution. Enlistment will be purely voluntarily, but all students over the age of 18 will be encouraged to enlist. The enlistment will constitute the student a member of the Army of the United States subject to active duty at the call of the President. It will, however, be the policy of the Government not to call the members of the training units to active service until they have reached the age 21, unless urgent military necessity compels an earlier call. Students under 18, and therefore not obliged to enlist, will be encouraged to enroll in the training units. Provision will be made for coördinating the Reserve Officers Training Corps system, which exists in about one-third of the collegiate institutions, with its broader plan.

This policy will accomplish a twofold object: First, to develop as a great military asset the large body of young men in the colleges; and second, to prevent unnecessary and wasteful depletion of the colleges through indiscriminate volunteering by offering to the students a definite and immediate military status.

High-Grade Men Wanted for Army Ordnance

An urgent call for high-grade technical men and operatives to fill war positions in industrial establishments was made May 13, through the Civil Service, by the United States Army Ordnance. Salaries ranging from $1600 to $6000 a year will be paid the men who qualify for the places.

Chemists and chemical engineers, men experienced in the manufacture of gas, mechanical engineers on high-pressure apparatus, engineers to take charge of power houses and foremen of machine shops are needed. Persons of military age accepting appointment will not avoid the obligations of the Selective Service Law.

No applications will be accepted from Government employees or employees of firms or corporations engaged in contracts for the Government or its Allies unless written assent to such application is given by the head of the establishment that might be seriously handicapped in its war work by the loss of the man.

Salaries ranging from $1600 to $2400 will be paid junior mechanical engineers on high-pressure apparatus. Experience in the operation and control of high-pressure hydraulic and gas machinery is necessary. At least one year of such experience will be required of graduates in mechanical-engineering courses from recognized colleges. Four years' experience is required of high-school graduates.

Power-house engineers will be paid $1800 to $2400 a year while working for the Ordnance Department. Supervision of operation of water-tube boilers, condensers, pumps, steam turbines and alternating- and direct-current generators and motors are among the duties of these men. Machine-shop foremen with salaries from $1800 to $2400 also are wanted. Ten years' experience as machinists, three years in a responsible supervisory capacity, is required.

Assistant operatives in the manufacture of water gas and producer gas, mechanics experienced on high-power apparatus, and operatives of acid and chemical apparatus are needed. Many positions are open. The needs of the service are so imperative that applications will be received indefinitely. Further information is obtainable of the Civilian Personnel Section, U. S. Army Ordnance, 1330 F St., Washington, D. C.

Women for the Drafting Room

In response to an appeal from the Government to help find engineering designers and draftsmen, Dean M. E. Cooley, of the University of Michigan, has suggested the plan of fitting women for tracers and as inspectors of materials. This would relieve men for the more important duties of draftsmen and designers and help fill places made vacant by the draft. Inquiries among engineers developed the fact that those who had employed women in such capacities were enthusiastic. They were particularly neat in their work, accurate and dependable. Due to shortage of help, other engineers were anxious to give them a trial. As a result, the University of Michigan has arranged as a war-time measure a summer course to prepare women for this new work. Similar action might well be taken by other engineering colleges of the country, and it should be to the interest of engineers to support the movement and help it along by employing the girls when they have received their training. In this connection the following resolution, passed at a joint meeting of the Detroit Engineering Society and the Detroit Section of the American Society of Mechanical Engineers, shows that the possibilities of employing women in the drafting room and allied work are appreciated, and that there is the desire to allow them to give direct help in winning the war:

Whereas, The demands of the country for men and means to fight the war have resulted in a deficiency of skilled workers in the trades and professions; and

Whereas, The women of this country could with a short period of training fit themselves to fill these positions, as women have done in other countries at war; and

Whereas, Among the things that women could do advantageously are drafting and tracing, inspection and testing of materials, both physically and chemically; therefore be it

Resolved, That the universities, colleges and technical schools throughout the land be asked to consider the question of meeting this demand by providing special courses of instruction open to women students qualified to pursue such courses; and further

Resolved, That employers who could use such skilled help exert their influence with their universities, colleges and technical schools, and coöperate with them in developing and making available a great body of intelligent and adaptable women who are as eager and willing to serve their country as their brothers; thereby bringing about not only increased effectiveness in fighting the war, but also a greater mutual respect and saner relationship of our men and women.

Control of Ice

New York State Senate Bill No. 605, an amendment, approved by the Governor and now law, states the following, in part:

The ice comptroller is hereby given power to regulate and control the manufacture of artificial ice in the City of New York, on Long Island, or in the counties bordering on the Hudson River, up to and including the Counties of Albany and Rensselaer; to regulate and control the storage and transportation of natural and artificial ice in said locality; and to regulate and control the sale, delivery and distribution of natural and artificial ice in any city having more than one million inhabitants. A person, partnership or corporation shall not manufacture artificial ice, for sale or any other purpose, in the City of New York, on Long Island or in the counties bordering on the Hudson River up to and including the Counties of Albany and Rensselaer, nor shall a person, partnership or corporation engage in the business of selling and delivering or distributing artificial or natural ice in any city having more than one million inhabitants after Mar. 1, 1918, or before Feb. 1, 1918, without first obtaining a license to be issued by the ice comptroller in a form and upon terms and conditions to be prescribed by him.

Heavy penalties are provided for violation of this law.

Area and surface are not synonymous, and sometimes men mix them up as did the man who corrugated a piston, thinking that in so doing he was increasing area and making his engine more powerful.—*Marine Engineering.*

West Virginia Water-Power Legislation

It seems highly probable that there will be water-power legislation at the next session of the West Virginia legislature which will convene in January, 1919. During the special session of May, 1917, the Senate adopted a resolution requesting Governor Cornwell to appoint a committee of three to investigate the water-power situation and to submit a report to the next legislature, with such recommendations as to future legislation to encourage development as the committee might deem necessary. The governor appointed as members of that committee the Hon. Wells Goodykoontz, president of the Senate, and Senators Fred L. Fox, of Sutton, and C. C. Coalter, of Hinton. Recently that committee held its first meeting but went no farther than to make arrangements to study the present laws and to take up at a later date the drafting of new water-power statutes.

It is generally conceded that the present water-power laws of the state are prohibitory so far as any development is concerned. This has been fully attested to by the fact that since the present statutes were enacted in 1915 there has been no water-power development except on a very limited scale, although there are in the state many streams that will furnish all the power needed for years to come. Owing to present conditions, therefore, a valuable resource is not being utilized and is in fact being allowed to go to waste. As this is a time when every resource and every ounce of energy must be utilized, sentiment for legislation which will encourage water-power development and yet fully protect the rights of the state is pronounced, especially in the New River and other sections where water power is available and only needs to be harnessed.

Thrift Stamp Day a Huge Success

Thrift Stamp Day in the United States has come to stay. The results of the first Thrift Stamp Day, May 6, were so satisfactory that the National War Savings Committee of Greater New York has decided to hereafter set aside every first day of each month as Thrift Stamp Day, and all business houses throughout the Greater City have been asked to coöperate and make a special drive to boost the sales of Thrift and War Savings Stamps on those days. The results of the first big Thrift Stamp Day has convinced the workers and the managers in charge of the drive that the setting aside of one day each month for a War Savings offensive would be a splendid idea.

The question of setting aside the first day of each month for Thrift Stamp Day was broached to the leading business men of the city, and they all received the idea with great enthusiasm. Special literature has been prepared for the occasion, and the thirty-odd thousand authorized agents of the Treasury Department have been asked to do at least as well on future Thrift Stamp days as they did on the first day.

New Publications

ESSENTIALS OF DRAFTING. By Carl L. Svensen. Published by D. Van Nostrand Co., New York. Cloth, 200 pages; 6 x 9 in.; 450 illustrations. Price, $1.50.

As a book prepared especially for the evening technical school it seems to be well suited for that purpose. The treatment of the various subjects is somewhat brief, as it is expected that personal instruction is also to be given. It is therefore not a strictly "self-instruction" book, but a guide for both student and instructor.

HANDBOOK ON PIPING. By Carl L. Svensen. Published by D. Van Nostrand Co., New York. Cloth, 359 pages; 6 x 9 in.; 359 illustrations and 8 folding plates. Price, $3.

An orderly presentation of the subject beginning with a short introductory chapter of ten pages, giving an insight into the history and manufacture of pipe, followed by six others treating of "dimensions and strength of pipe, pipe threads, pipe fittings, pipe joints, standard valves and special valves." Chapters 8 to 15 deal with piping systems under the following heads: Steam piping, drip and blowoff piping, exhaust piping and condensers, feed-water heaters, piping for heating systems, water and hydraulic piping, compressed air, gas and oil piping, erection, workmanship and miscellaneous. Chapter 16 is on piping insulation, Chapter 17 on piping drawings, and the closing chapter—specifications—contains the Stone & Webster standard piping specifications and a model specification by the Walworth Manufacturing Co. The eight folding plates referred to are reproductions of the piping drawings, by Stone & Webster, for the Cannon Street Station of the New Bedford (Mass.) Gas and Edison Light Co. While this book is frankly a compilation of information and tables considered standard and the illustrations are mainly from manufacturers' catalogs, it contains much information that, when brought together in this manner, is readily accessible when needed by the engineer or student.

Personals

Edw. A. Cordes has tendered his resignation to take effect July 1, as master mechanic for the Babcock & Wilcox Co., at Barberton, Ohio. He will locate in Chicago, Ill.

H. D. Wright, who has been manager of the San Francisco office of the Brown Hoisting Machinery Co., has been appointed Pacific Coast representative, succeeding the Colby Engineering Co. in the northwest territory.

Engineering Affairs

The Society for the Promotion of Engineering Education will hold its twenty-sixth annual meeting at the Northwestern University, Evanston, Ill., June 26-29. The subject of discussion will be "The Engineering School and the War."

The Iowa Section of the National Electric Light Association will hold its convention May 31 and June 1, at Des Moines. The subjects to be discussed are as follows: The Labor Situation, by T. Crawford, Clinton, Iowa; Isolated Plants, by Austin Burton, Waterloo, Iowa; Rate Increase, by F A. Warfield, Peoria, Ill.; The Coal Situation, by F. W. Linebaugh, Boone, Iowa; Boiler-Room Economy, by E. S. Hight, Peoria, Ill

Miscellaneous News

A Furnace Boiler Exploded in the basement of the Russell House, Montreal, Canada, on May 11, injuring five persons who happened to be in or near the hotel at the time. It is said the explosion was caused by someone having turned off the water from the furnace.

The First Commercial Shipment of coal from the mine operated by the Alaskan Engineering Commission was made in the last week of April. A consignment of 100 tons from the Chickaloon field went to Seattle, Wash., on the steamship "Alameda." The coal was shipped in sacks under a freight rate of $5 per ton for shipments of 100 tons or more and $7.50 per ton on shipments less than 100 tons.

A Wire from Folsom to the Washington State Fuel Administrator, dated May 10, announces that "We are advised that a large number of tankers are to be withdrawn from the Pacific Ocean for Atlantic service within six months. This will necessitate changing of Northwestern industries to coal wherever possible, regardless of cost." It is understood that oil consumers in the Northwest who cannot change to coal will be required to submit by June 10 a statement giving the nature of their business and reasons for not making the change.

The City of Pasadena and the Southern California Edison Co. have filed a joint application with the California Railroad Commission asking for permission to lease the company's distributing system to the city for two years with an option of purchase. The city is to pay rental on a basis of 8 per cent. on the valuation of $513,102, with an additional rental for extensions made after Dec. 31, 1918. Under the terms of the lease the city is to purchase power from the company for a price ranging from 0.0095c. per kw.-hr. for the first 250,000 kw.-hr. to 0.0075c. for all over 750,000 kw.-hr. Pasadena agrees to lease all of its lines and distributing system outside of the city for a rental basis of 8 per cent. on a valuation of $27,928.

At the Del Monte Convention a letter from the Pacific Coast Petroleum Administrator, D. M. Folsom, was read, which stated that even with the most careful economies, the oil stored on the Pacific Coast will be exhausted within a year and the curtailment of consumption may be expected within six months or less. There has been a decline in drilling operations thus far this year of 40 per cent. as compared to last year. All fuel-oil consumers will probably be classified and only those entitled to priority rating will be supplied with oil. In the case of companies which use oil for generating power, the oil supply will be continued only if consumers served are entitled to priority rating and the burden of proof that consumers are entitled to such rating will rest upon the power companies.

Cleveland Plants Interconnected—An agreement recently made between the Cleveland Municipal Light plant and the Cleveland Electric Illuminating Co., through the National Council of Defense, will result in the interchange of power output between the two stations. An overhead connection is to be built immediately between the East 53rd Street Municipal plant and the Cleveland Illuminating Co. at East 72nd St. to provide interchange of power in case either plant breaks down. This practically guarantees war plants against stoppage of work through accident. The connection will cost $90,000. It will be financed by the Council of National Defense. Government officials agree to speedy delivery of the city's new 10,000-kw. generator, so that it will be ready to increase the municipal plant's current by fall instead of by Jan. 1.

The U. S. Circuit Court of Appeals recently reversed the decision of a lower court in the famous Elk Hills suit between the Southern Pacific and the Government on the ownership of California oil fields. In discussing this, Paul Shoup, president of the Pacific Electric Railway Co., Los Angeles, who has recently been at Washington, said that a compromise on the suit for the duration of the war is to be forthcoming very soon and that these lands which have so long been tied up in litigation will probably be opened up and developed at an early date in the most expeditious manner. Nevertheless drastic measures in curtailing the consumption of oil will doubtless be put into effect. Embargoes and restrictions of oil shipments and oil consumption generally may be expected.

NEW CONSTRUCTION

Proposed Work

N. H., Derry—The Derry Electric Light Co. plans to extend its electric transmission line from here to East Derry. D. F. Griffith, Supt.

Mass., Boston—The Board of Education will soon award the contract for the installation of a direct radiation system in the public and high school. Estimated cost, $20,000. J. J. Mahar, City Hall Annex, Consulting Engr.

Mass., Brookline—The Town is in the market for equipment for its incinerator including a steel apron conveyor complete with steel chute, motor and connections, 2 paper baling presses with motors and connections, etc. A. Varney, Engr.

N. Y., Buffalo—Cousins & Co., 74 Wahash St. will soon award the contract for the erection of a 1 story, 95 x 125 ft., reinforced concrete steel and brick boiler plant. Estimated cost, $35,000. Noted Dec. 11.

N. Y., Brooklyn—The Bureau of Supplies and Accounts, Navy Dept., Wash., will soon receive bids for furnishing at Navy Yard, here, under Schedule No. 1812, Klinger type, water gage, reflex glasses; under Schedule No. 1808, mechanical thermometers, mercury for thermostats thermometers, 4000 common mercurial thermometers, 2000 water thermometers, 2000 maximum and minimum thermometers and 1000 mercury, storage battery thermometers.

N. Y., Brooklyn—The Bush Terminal Co., 100 Bway., New York City, plans to build an addition to its local transformer station.

N. J., Hoboken—The Remington Arms Co. has awarded the contract for the erection of a 1 story, 81 x 160 ft. factory, to the Austin Co., 16,112 Euclid Ave., Cleveland, Ohio, $40,000. A low pressure boiler for steam heat will be installed by owner.

N. J., Jersey City—The Central Railroad of New Jersey, Communipaw Ave., has had plans prepared for the erection of a local power house. Estimated cost, $50,000. A. E. Owens, New York City, Ch. Engr.

N. J., Newark—The Heller and Merz Co., Hamburg Place, will soon award the contract for the erection of a power house. R. G. Corey, 39 Cortland St., New York City, Archt. Noted May 14.

N. J., Newton—The Sussex Print Works will soon award the contract for the erection of a 50 x 50 ft. addition to its power plant. Estimated cost, $10,000. A. Kidd, Jr., 95 Liberty St., New York City, Arch.

N. J., Woodbridge—Bids will be received until June 3, by the Township Committee for the installation of a heating system in its new municipal building. A. Keyes, Clerk.

Penn., McKeesport—The McKeesport Tinplate Co. plans to install a steam power plant in its mills here. Estimated cost, $1,200,000.

Penn., Philadelphia—The Bureau of Yards and Docks, Navy Dept., Wash., D. C., is receiving bids for the erection of a new power plant at the aircraft factory on League Island.

Wash., D. C.—The Bureau of Supplies and Accounts, Navy Dept., Wash., D. C., will soon receive bids for furnishing at various Navy Yards, under Schedule No. 1806, steam pressure gages.

Va., Norfolk—The Bureau Yards and Docks, Navy Dept., Wash., D. C., is having plans prepared for the installation of an electric lighting and power system in Shipbuilding Slip No. 1. Estimated cost, $15,000.

W. Va., Junior—The Gage Coal and Coke Co. plans to install a 150 kw. 250-275 volt generator in its mine.

S. C., Charleston—The Bureau of Supplies and Accounts, Navy Dept., Wash., will soon receive bids for furnishing at Navy Yard here under Schedule No. 1817, regular, steam and water, seamless drawn, brass pipe; extra strong, steam and water, seamless drawn, brass pipe; regular seamless drawn copper pipe; hard drawn, seamless brass tubing in commercial lengths and hard drawn, seamless copper tubing in commercial lengths.

Ga., Acworth—The Acworth Hosiery Mills is considering plans for the installation of electrically driven knitting machines. Estimated cost, $10,000.

Tenn., Lenoir City—The Public Light and Power Co. of Chattanooga plans to rebuild its electric transmission line from here to Rockwood. W. R. Stern, Winchester, Mgr.

Ohio, Cincinnati—The G. B. Curd Co., 602 Merchants Library Bldg., plans to build a 1 story, 40 x 60 ft. boiler shop on Highland Ave.

Ark., Helena—The A. M. Richardson Lumber Co., recently incorporated, is in the market for power plant equipment.

Tex., Brackettsville—The City plans to extend and improve its electric lighting plant.

Tex., Knippa—C. A. Lindsay, 203-4th Natl. Bank Bldg., Wichita, Kan., and associates, are having preliminary surveys made for a hydro electric plant and an irrigation system on the Frio River near here.

Tex., Mercedes—The Mercedes Water, Light and Power Co. is in the market for a new 100 hp. engine and new generator.

Okla., Miami—The Lightfoot Oil and Mining Co. is in the market for engines, boilers, etc., to install in its proposed concentration mill soon to be erected. Total estimated cost, $100,000. W. Lightfoot, Supt.

Okla., Oklahoma—The Chickasaw Hosiery Mill plans to build a large plant. Plans include the installation of 150 hp. steam and electric power plant, etc.

Okla., Prague—The City will soon award the contract for the erection of a 22 mile transmission line south and west of here to connect with the system of the Oklahoma Power and Transmission Co. The work includes the construction of a sub-station and the installation of three 75 kva. 33,000 to 2300 volt, 60 cycle, single phase, transformers, two 500 gpm., 220 ft. lift, direct connected, motor driven, centrifugal pumps, etc. R. Parks, Mayor.

Idaho, Sandpoint—The Falls Creek Mining Co. plans to install a power plant.

Wash., Seattle—The Northwest Trading Co., L. C. Smith Bldg., is in the market for electric lighting and power plant equipment including a turbine generating set directly connected, a three-phase, 6600 volts, 5 cycles, electrical system, etc.

Wash., Waterville—The Chelan Falls Power Co. has petitioned the Douglas County Commissioners for authority to build a transmission line here.

Ore., Astoria—The Hammond Lumber Co. plans to install additional electric power equipment including a turbine and generator and four 600 hp. water tube boilers.

Ore., Portland—The Pacific Power and Light Co. plans to build a 660 volt, 3 phase transmission line from here to the plant of the Utah Idaho Sugar Co. I. C. Martin, Engr.

Ore., Reedsport—The Umpqua Light and Power Co. is having preliminary plans prepared for the erection of a transmission line over the Umpqua River.

Calif., Bolinas—The Chetco Mining Co. plans to install electrically driven pumping equipment in its plant here.

N. S., New Watford—The Dominion Coal Co., Sydney, plans extensive power developments including the erection of a central power station here.

Que., Grand Mere—The Laurentide Power Co. plans to install 3 additional units, 20,000 hp. each. J. Ruddick, Beaupre, Engr.

Ont., Sault Ste. Marie—The Great Lakes Power Co. plans to rebuild its power plant which was recently destroyed by fire. A. E. Pickering, Mgr.

Ont., Thedford—The Town plans to install a lighting and power system. W. Brookes, Clerk.

Sask., Regina—The City is in the market for a 5000 kw. electric unit. Estimated cost between $175,000 an $200,000. G. Beach, Clerk.

B. C., Revelstoke—The Lanark Mines Co. plans to build a power plant and install equipment in same. W. B. Dornberg, Spokane, Wash., Mgr.

H. T., Pearl Harbor—The Bureau of Yards and Docks, Navy Dept., Wash., D. C., is having plans prepared for additions and improvements to the power plant here. Estimated cost, $150,000.

CONTRACTS AWARDED

Ohio, Cleveland—The Illuminating Co., Illuminating Bldg., has awarded the contract for the erection of a 1-story, 35 x 168 ft. addition to its power house on East 70th St., to the National Concrete and Fireproof Co., 1315 Citizens Bldg., $60 000. The owner is in the market for electric equipment, switch boards, etc.

Ohio, Columbus—The Board of Education has awarded the contract for a heating and lighting system in the shop school wing to the Huffman-Conklin Plumbing Co., 669 North High St., Erie, Penn. Estimated cost, $27,500.

Okla., Miami—The Mint Mining Co. is building a concentration plant. Estimated cost, $100,000. Work includes the installation of boilers, engines, etc. J. Labsap, Supt.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular Current	Individual Current
Buckwheat	$4.60	$7.10—7.35
Rice	4.10	6.65—6.90
Boiler	3.90	....
Barley	3.60	6.15—6.40

BITUMINOUS

Bituminous not on market.

Pocohontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.00 a year ago.

*All-rail to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o b. Tidewater at the lower ports* are as follows:

ANTHRACITE

	Circular Current	Individual Current
Pea	$4.90	$5.65
Buckwheat	4.45@5.15	4.80@5.50
Barley	3.40@3.65	3.80@4.50
Rice	3.90@4.10	3.00@4.00
Boiler	3.65@3.90	....

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Gross	Mine Price Net	Gross
Central Pennsylvania..	$5.06	$3.05	$3.41
Maryland—			
Mine-run	4.84	2.85	3.19
Prepared	5.06	5.05	3.41
Screenings	4.50	2.55	2.85

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty, Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The ratte to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Current	One Yr. Ago	Current	One Yr. Ago
Pea	$3.45	$3.00	$4.35	$3.90
Barley	2.15	1.50	2.40	1.75
Buckwheat ..	3.15	2.50	3.75	3.40
Rice	2.65	2.00	3.65	3.00
Boiler	2.45	1.80	3.55	2.90

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes...	$2.65—2.80	$3.35—3.50
Mine-run	2.40—2.55	3.10—3.25
Screenings	2.15—2.30	2.85—3.00

Smokeless Coals	So. Ill., Pocohontas. Pennsylvania and W. Va.	Hocking.East Kentucky and West Va. Splint
Prepared sizes...	$2.60—2.85	$2.85—3.35
Mine-run	2.40—2.60	2.60—3.00
Screenings	2.10—2.55	2.35—2.75

St. Louis—Prices per net ton f.o.b. mines are as follows:

	Williamson and Franklin Counties	Mt. Olive & Staunton	Standard
6-in. lump	$2.65-3.00	$2.65-2.80	$2.65-2.80
2-in. lump	2.65-3.00	2.65-2.80	2.25-2.50
Steam egg....	2.65-2.80	2.35-2.50	2.25-2.40
Mine-run	2.45-2.60	2.45-2.60	2.45-2.60
No. 1 nut.....	2.65-3.00	2.65-2.80	2.65-2.80

The Fellows Who Know

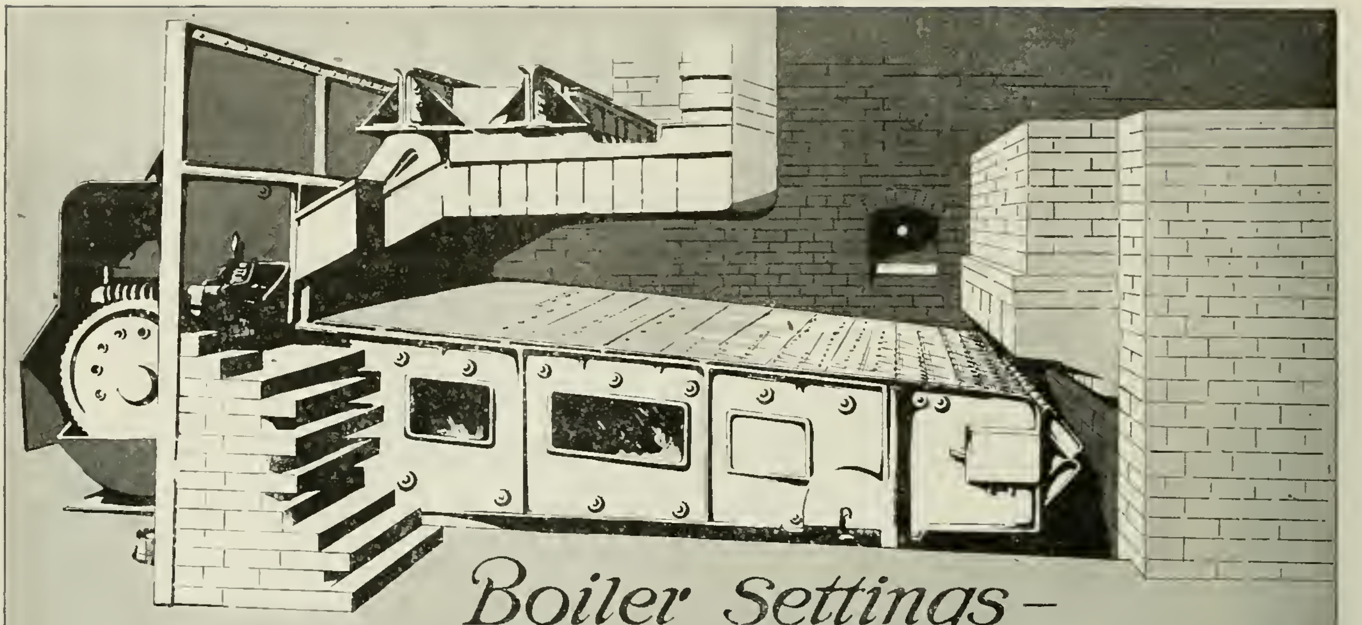
By RUFUS T. STROHM

SADLY enough, in this era of trickery,
  Humans are trying to be what they're not,
Heedless that coffee compounded with chicory
  Seldom can pass through the test of the pot.
Thus, though pretenders may capture the galleries
  And by audacity garner the dough,
Still, in the long run, the choicest of salaries
  Drop in the jeans of the fellows who know.

SOME of the ignorant, wantonly venturing,
  Knowing they're either dead right or dead wrong,
Blind to the danger and deaf to the censuring,
  Trust to their bluffing to help them along;
Thus, while they're constantly fearful and quavering,
  Wondering whether they'll stay or they'll go,
No such alarms or suspicions of wavering
  Trouble the lives of the fellows who know.

BLUFF and deception may win temporarily,
  Leaving Old Honesty far in the rear,
Still, prudent folks will consider them warily,
  Choosing instead to be strictly sincere.
No reputations of worth and solidity
  Out of imposture and knavery grow,
Yet recognition with pleasing rapidity
  Comes to the doors of the fellows who know.

GUESSWORK is weakness—a sand rope whose rottenness
  Millions of toilers still stupidly try,
Though it betrays into lasting forgottenness
  Those who so foolishly on it rely.
Knowledge is power, and men of sagacity,
  Yearning for honors the world can bestow,
Ceaselessly striving for increased capacity,
  Share the rewards of the fellows who know.



Boiler Settings—Chain Grate Stokers*

by CHARLES H. BROMLEY
Associate Editor of Power

One of several articles on boiler settings for various boilers and types of stokers most suitable for the different coals. The chief purpose of the articles is to assist those in the Middle West and Northwest who are confronted with combustion problems by reason of the zone system for the distribution of bituminous coal enforced by the Fuel Administration. Several excellent chain-grate settings are shown in this article.

ONE does not have to argue the adaptability of the chain-grate stoker for the coals of the Middle West and Northwest, or, as they are sometimes called, Eastern Interior coals. They have demonstrated it. The writer does not, however, indorse the statement that this type alone is *most* suitable for these coals. This claim defied refutation until recently because the underfeed stoker had not shown what it could do with them. The chain grate is admirably suited to these coals where the load conditions do not impose boiler ratings of more than 250 per cent. of builders' rating.

The chain grate, like all other stokers, frequently suffers because of poorly adapted boiler settings. Sometimes these are unavoidable; that is, in places where sufficient headroom is not available for raising the boilers, where conditions prohibit lowering the stoker or floor line, or because the purchaser is obstinate or wants "something nearly as good for less money." The builder, therefore, cannot always put in his ideal setting.

The seriousness of this is felt, especially during times like these when coals of considerably poorer grades than those for which the setting is at all adapted find their way into the plant. High settings with correct arches originally installed, avoid troubles due to using coals of widely varying volatile content, and where high combustion rates are necessary or may become so.

Some excellent chain-grate settings are shown herewith. Notice that no secondary arch is used with this particular stoker, the arch being very long. Fig. 1 shows a Stirling boiler, and what strikes the observer as unusual is the absence of a secondary arch, simplifying construction, though not appreciably increasing maintenance charges.

Where secondary arches are provided, they do not always exert any appreciable effect, at least upon the incoming coal, owing to the curtain wall between the two arches. The arch in Fig. 1 is effective over the whole fuel bed. This is important where smokelessness and high combustion rates are needed, because with a chain-grate stoker the resistance to the fuel bed is comparatively small and the thickness, density and porosity of the fuel bed do not conduce to such thorough mixture of air and gases *in the fuel bed* as with an underfeed fire, high combustion rates considered. The arch is, of course, ventilated.

The height of a Stirling boiler setting is taken as the distance from the center of the bottom drum to the floor line. The setting, Fig. 1, would be improved for Middle Western coals if this was 6 ft. instead of 5 ft., as shown. Have in mind that this applies to the chain grate; for the underfeed stoker it should be at least 1½ ft. higher. For lignite combustion would be improved if the setting were not less than 8 ft. The author bases this opinion upon recent performances of underfeed stokers burning lignite.

Broadly, it may be said that the tubes of a Stirling boiler should always be exposed to the direct heat of the furnace gases and fuel bed. In fact, it is the writer's opinion that tubes immediately above the fire should never be covered with C tile or with any other material

---

*For previous articles see the following issues "Power": "Zone System for the Distribution of Bituminous Coal," May 14; "Coals of the United States," May 21; "Boiler Settings," May 28.

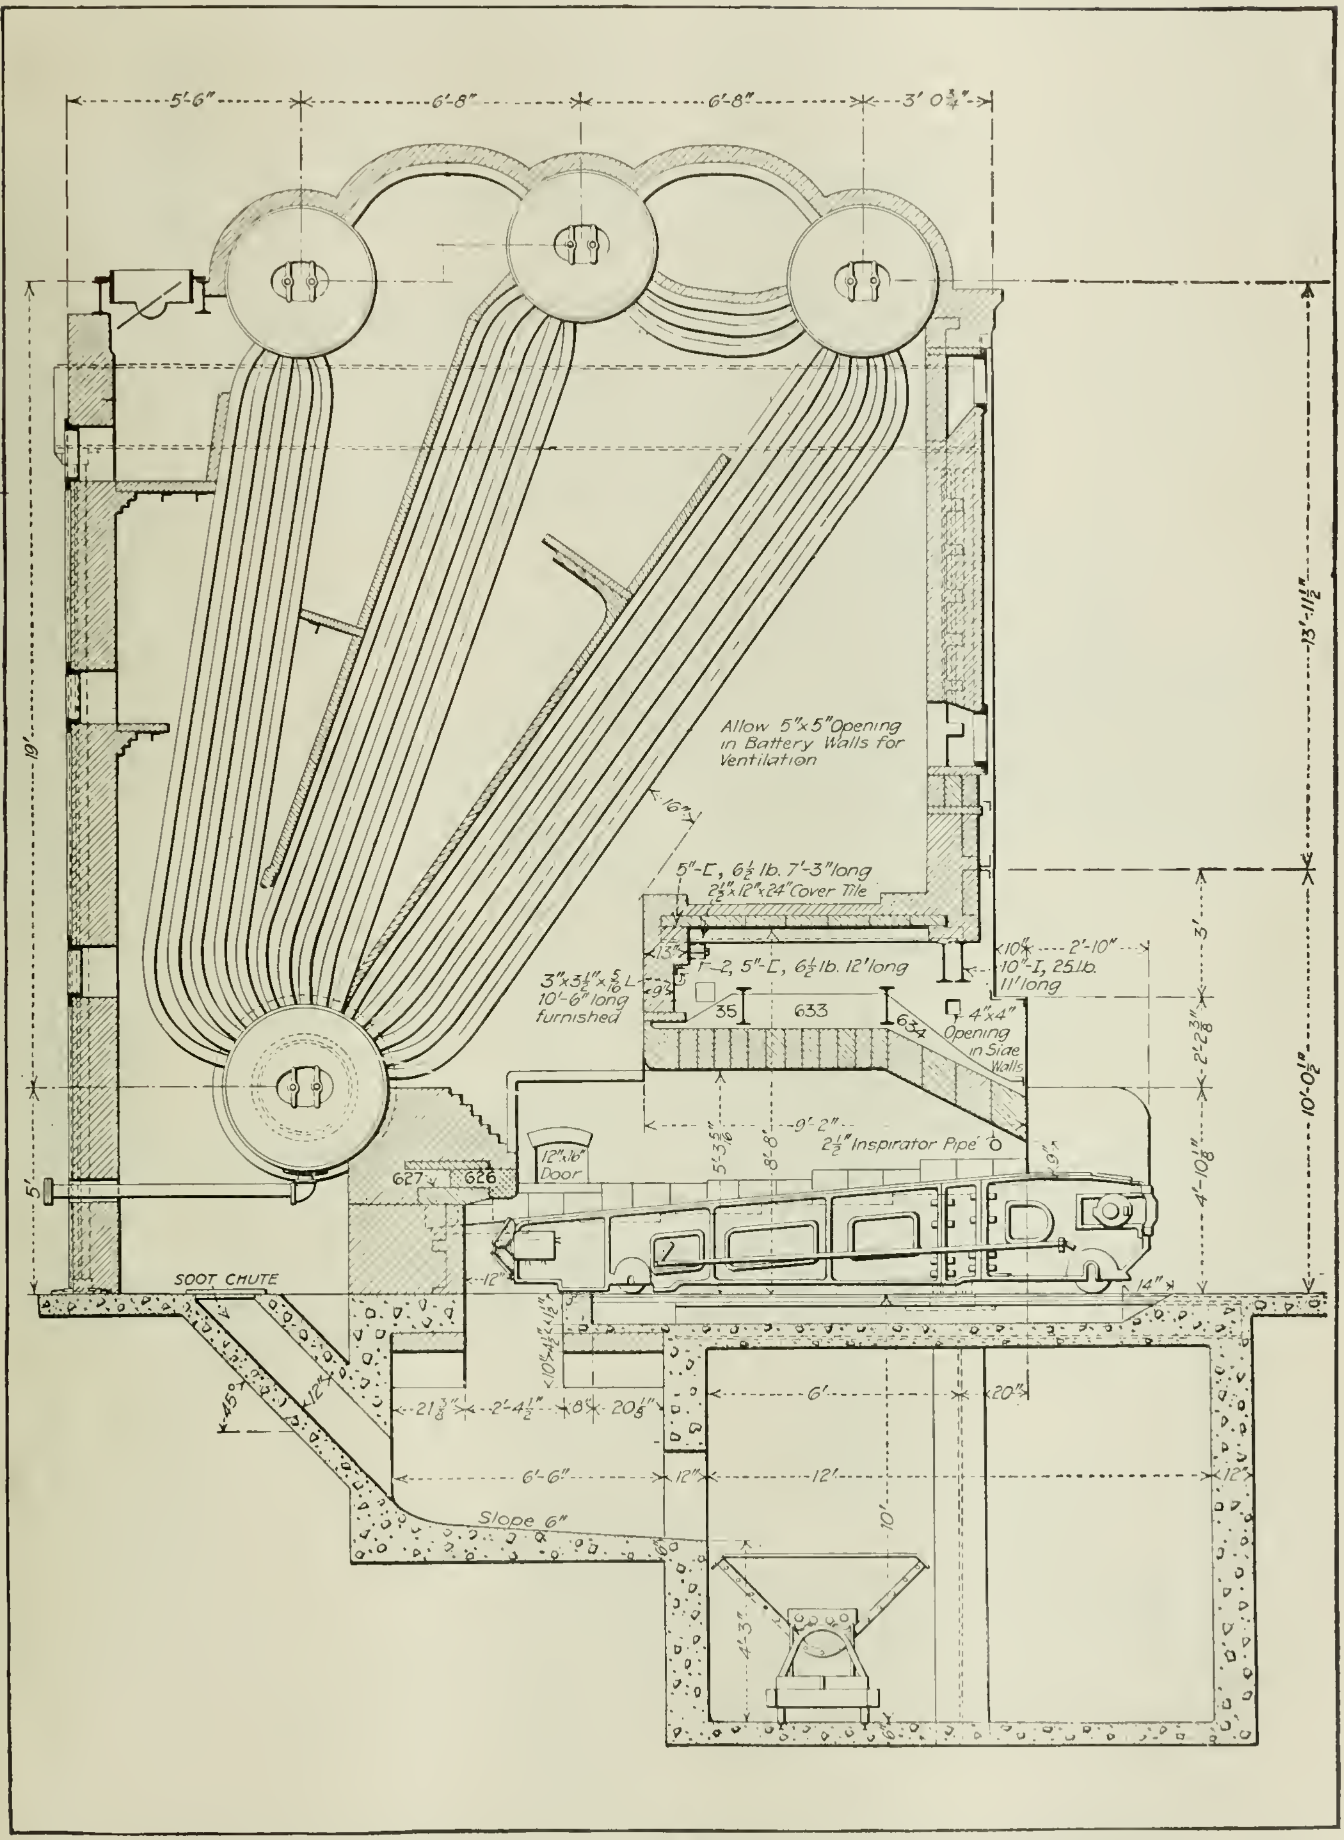


FIG. 1. EXCELLENT CHAIN-GRATE STOKER SETTING FOR BOILERS OF STIRLING TYPE

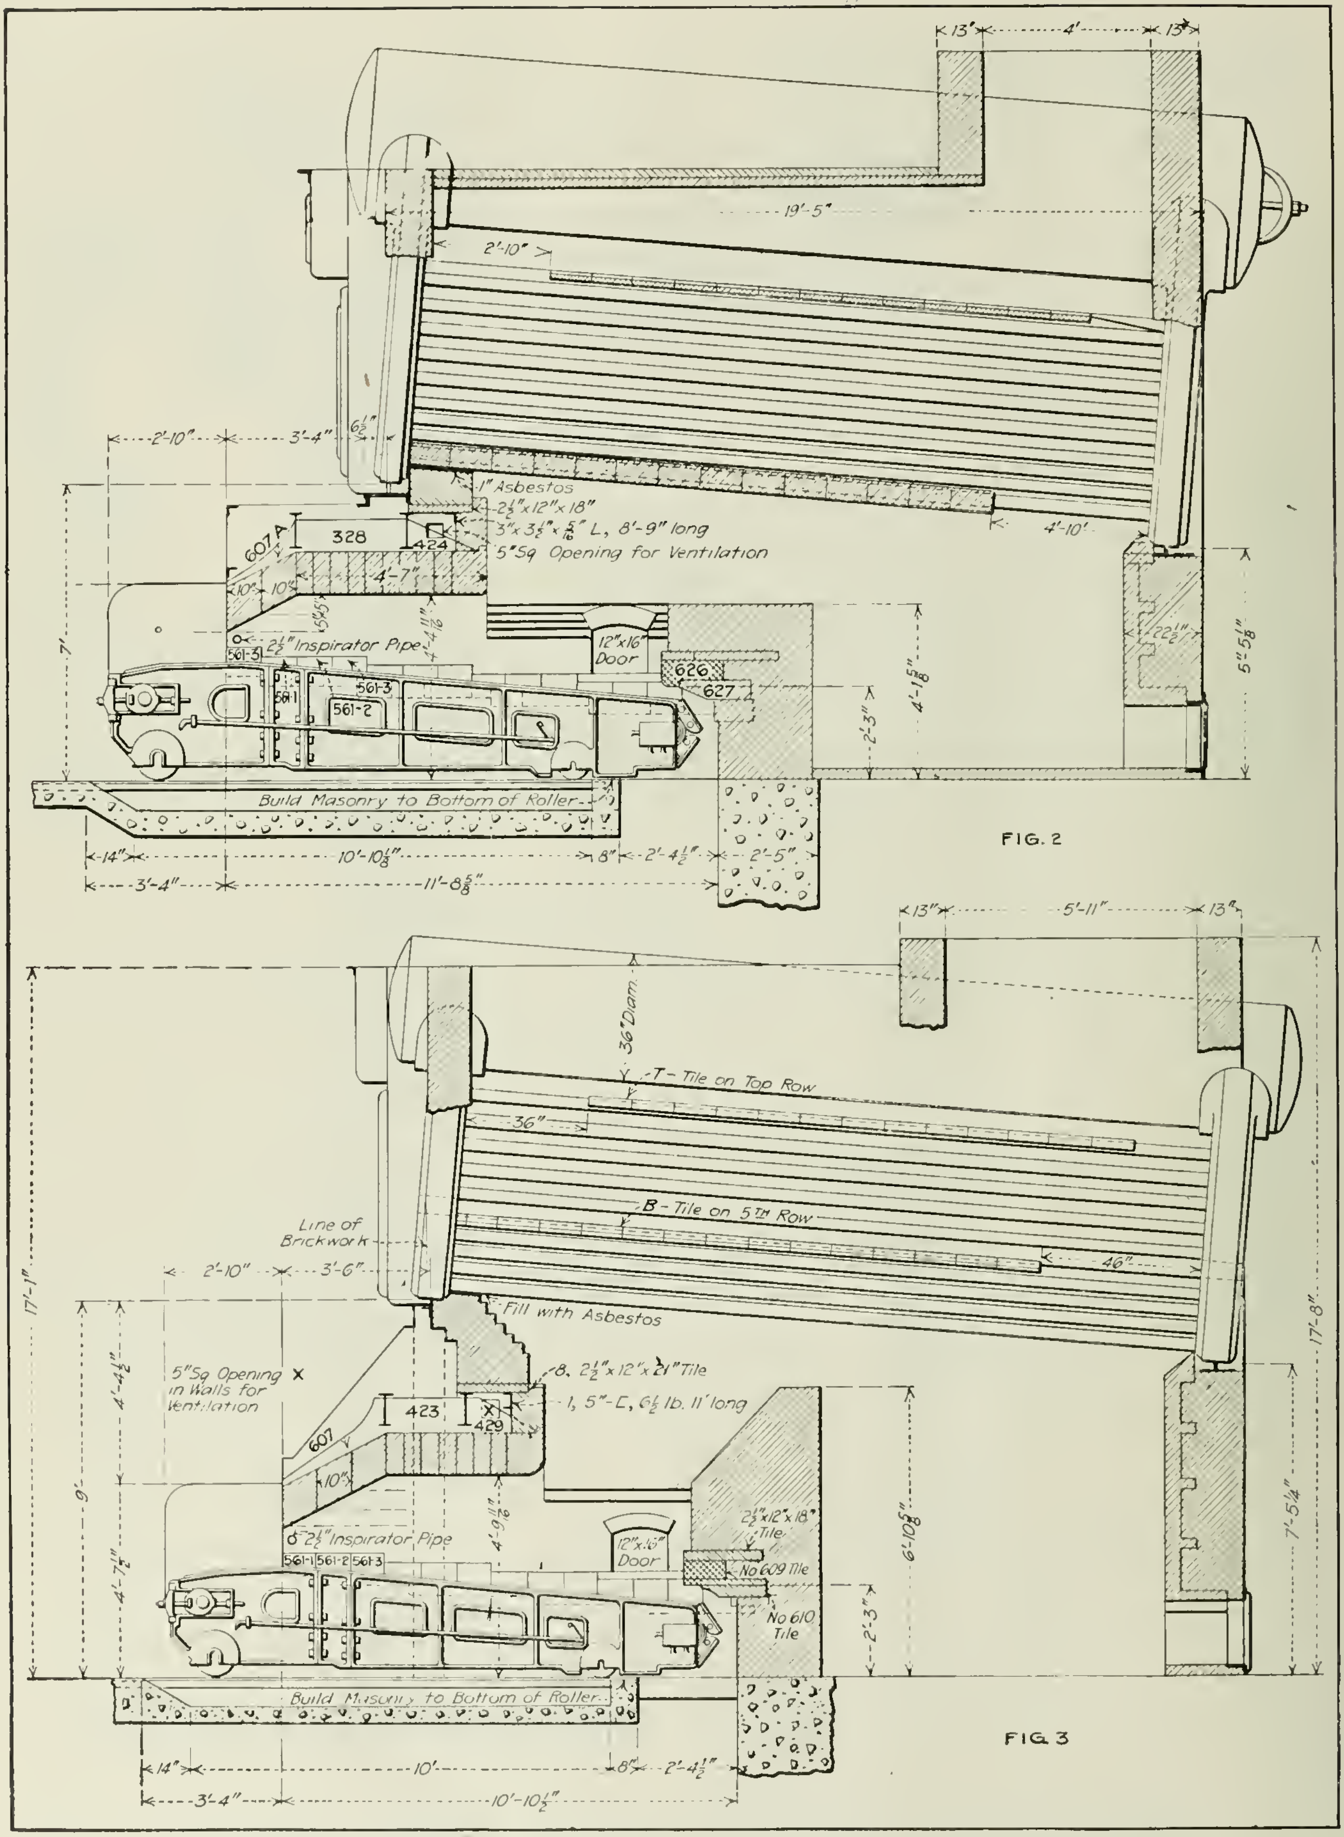
The setting would be improved if the distance between center of mud drum and floor was 6 ft. instead of 5 ft. Notice that no secondary arch is used.



FIGS. 2 AND 3. CHAIN-GRATE STOKER SETTINGS, BOILERS HORIZONTALLY BAFFLED
Fig. 2—The objection is that the setting is too low and that the baffle is on the lowest row of tubes. Fig 3—A good setting; notice baffle is on the fifth row of tubes

that completely covers them, shutting out the radiant heat of the fire. This applies to any boiler. Some tubes should be exposed to the direct heat; this avoids excessive tube failures and better distributes the evaporation per square foot of tube surface of the boiler.

The setting shown in Fig. 1 is installed in a famous soap manufactory in Kansas City, Kan. Notice that no water-back is used; bauxite tile, furnished by the stoker builder, is provided. The number referring to the bricks denotes the trade designation.

Fig. 3 shows an excellent setting for water-tube boilers of the type illustrated. The boiler is 9 ft. above the floor, insuring large combustion volume. Combustion would be improved if it were 10 ft., and for lignite, 12 ft. The arch is the same as in Fig. 1. The bottom tile is on the fifth row of tubes. This seems a little high; but it is probable that there will soon be a universal abandonment of tile on the very bottom row. It is the writer's belief that the boiler manufacturers would welcome this change. Fig. 2 shows a setting for a horizontal baffle boiler with the tile on the bottom row of tubes.

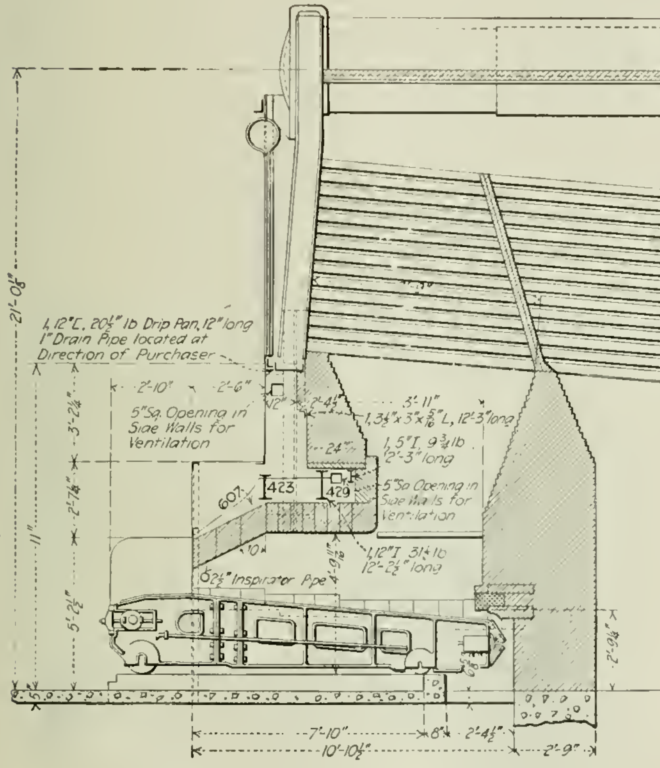


FIG. 4. AN 11-FT. SETTING FOR HIGH-VOLATILE COAL

The setting in Fig. 4, for a vertical baffled boiler, is good practice. The boiler is set high, being 11 ft. above the floor, and the arch and bridge-wall insure a fairly good mixture of air and combustible gases.

The baffling is designed to give an approximately uniform gas velocity throughout the entire flame travel. The setting is adapted for any Middle Western coal. Notice that the flame plunges directly among the tubes from the incandescent zone. The high setting permits of this, but only a high setting permits of it.

Fig. 5 shows a good setting for an Erie City boiler or any boiler of this general type. All the important dimensions are given.

Where lignite or slack high in moisture is to be burned on a chain grate, the reflecting arch is to be recommended. Some excellent settings using these arches, the function of which is to throw the flame forward so that the heat may assist in evaporating the moisture from the coal as the latter comes onto the grate, were shown in *Power* for Apr. 2, 1918, p. 472, and Apr. 30, 1918, p. 611.

The Standardization Committee of the Smoke Prevention Associations recently recommended the following:

> Water-tube boilers are constructed of tubes having 1 in. pitch to the foot, 1½ in. pitch to the foot and 3¼ in. pitch to the foot. Chain grates are of two kinds, the horizontal and the inclined grate, and the height of the boiler setting is determined from the vertical line immediately back of the front boiler header to the water-back of the stoker. This distance we propose as being five feet, and means that the water-back is located five feet back of the inner side of the front header. Three feet in front of the water-back a line is drawn that measures seven feet from the under side of the lower tube [row of tubes?] to the top of the grate. This standardizes all chain-grate stokers on all horizontal water-tube boilers, and is applicable to all settings requiring only 50 per cent. overload. [50 per cent. more than builders' rating?] If larger overloads, such as 200 or 250 per cent. rating, are required, this line should be extended about three feet.

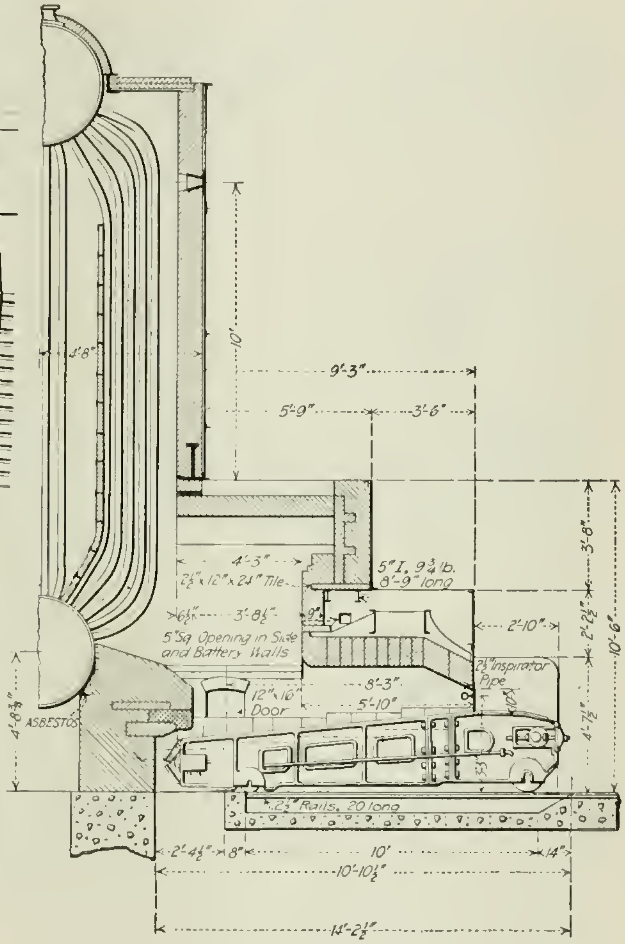

FIG. 5. FOR ERIE CITY AND SIMILAR BOILERS

The dimensions given will be found satisfactory for the coals of the Middle West, but it is probable that for lignite the settings should be 2 ft. higher. Experience indicates that lignite needs extraordinarily high setting.

If the moisture is 15 per cent. or more, a reflecting arch, after the fashion of Fig. 6, will be found a valuable aid to combustion, as such an arch sweeps the flame forward, evaporating the moisture in the coking region, thus avoiding serious loss of temperature at the surface of the fuel bed. In Fig. 6 *A* shows the arch applied to a step-grate stoker, *B* to a chain-grate stoker.

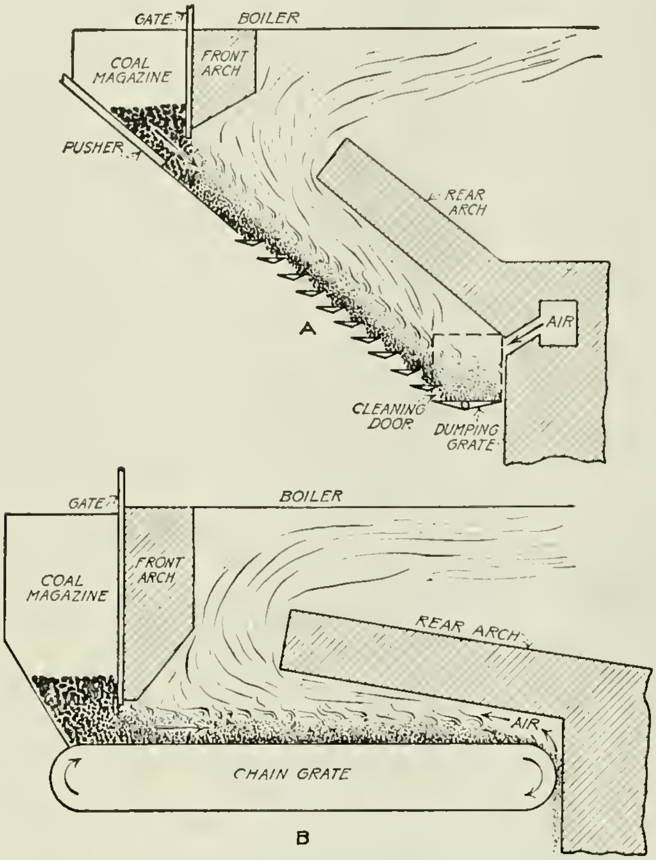

FIG. 6. REFLECTING ARCHES FOR LIGNITE AND HIGH MOISTURE COALS SUGGESTED BY KREISINGER OF THE BUREAU OF MINES; A, STEP-GRATE; B, CHAIN GRATE

Fig. 7 shows a setting recently developed by the American Radiator Co. for burning lignite in heating boilers. Notice there are no grates, that the coal feeds down when a shovelful or two of ash is removed. The writer does not have any performance data on this setting, but it may suggest something to those interested in furnace design for lignite under power boilers. The distribution of air is interesting.

Condenser Was Full of Ammonia

By T. T. Grover

After having operated without trouble for two years, a small packing-house refrigerating plant showed excessive head pressure. The trouble started in the early spring while the condensing water, which was taken from a river, was something like 38 deg. It was evident that if the pressure was more than normally high at this time, it would practically render the plant inoperative in summer when the water temperature went up to 80 to 85 degrees.

The plant had been superficially overhauled during the winter, and the condenser coils, which were of the atmospheric type, had been scraped and the scale removed. The only reasonable conclusion was that considerable air had been drawn into the system during the overhauling and the operators forthwith proceeded to purge the condenser.

A considerable portion of the ammonia charge had disappeared; the condenser pressure remained nearly as high as before and gradually got higher as the water temperature increased.

The heavy summer load was coming on, and the operators were at their wits end as to what to do about it. Finally it was concluded that the only remedy was to increase the condenser capacity by adding more stands to the ten already in service. Before deciding on this point, however, the chief called in the writer to investigate the problem and if necessary add more weight to the request for a larger condenser when it was put up to the management.

After purging the condenser once more and testing the pressure gages and doing everything else that I could think of, the head pressure still remained much too high. After roughly estimating the amount of gas handled by the condenser, I found that it was doing only about two-thirds of its normal capacity, based on the manufacturer's rating and from my experience.

I went over the condenser a second time, putting my hand on each stand to see if all the coils were working—something I had neglected to do the first time. To my surprise one-half of them were at the temperature of the condensing water. This pointed to the coils being airbound, and I at once got busy and purged them again.

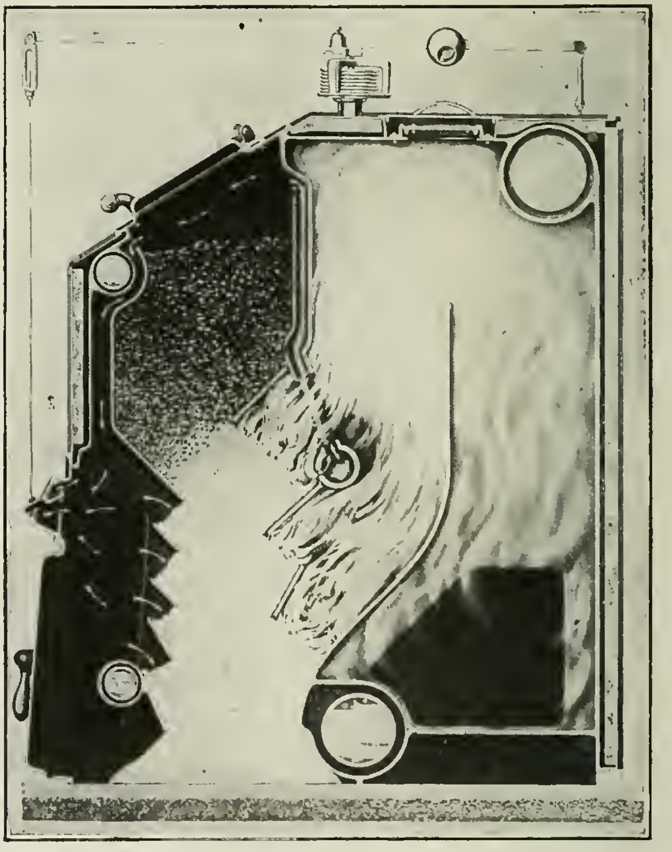

FIG. 7. FURNACE FOR BURNING LIGNITE IN HEATING BOILERS; NO GRATES ARE USED

To my surprise there was practically no sign of air; after it had been blowing for a few seconds, there was the unmistakable crackling of the water in the barrel that I was purging the coils into, that is always an indication that mainly all ammonia is coming from the coil that is purged. It had no effect on the condenser pressure. Evidently, it was not air or foul gases in the condenser that was causing the trouble. Furthermore, if there was no air in the coils, it was a foregone conclusion that they were full to the top with liquid, as otherwise the dead coils would have been of the same temperature as the others.

The only logical explanation was that the outlet from the coils to the liquid line was blocked in some way, and this assumption was not unreasonable after I investigated the connections at the bottom where each coil connected to the liquid line. The coils of the condenser were made up of 2-in. pipe, and at the bottom, where they connected to the liquid line, this had been reduced to ½-in. by means of a reducing elbow. Evidently, scale or other foreign matter had accumulated in the coil and collected at the reduced point in sufficient quantities to entirely block the passage.

The remedy was quite simple. I shut off all the dead coils at both ends and pumped them out until the pressure was down to atmosphere. The rest of the system was pumped down so that when the dead coils finally were pumped down to near atmospheric pressure, there was about 225 lb. pressure on the coils that were working. Leaving the pump-out connection to the dead coils open and the valve on the discharge end of the coils shut, I quickly opened the valve in the connection between the coil and liquid line for a few moments. This put a pressure of about 225 lb. on the blocked section and in the reverse direction of the normal flow, and it cleared it immediately as was evidenced by the coil frosting at once and the suction pressure "taking a jump."

When the plant was settled down to normal operation again, the head pressure was down to 125 lb. as against 175 lb. Also, there was an abundant supply of ammonia. With the coils blocked, the liquid had accumulated in the coils every time they had been purged until they probably were full up to the top at the time the trouble was discovered. At first, when there was considerable air in the condenser, this accumulated in the dead coils and prevented a large accumulation of liquid, but as this was gradually blown out, the coils slowly filled up, and this explained the gradual disappearance of the ammonia.

Power Loss in Waterwheel Pit

BY DAVID R. SHEARER

Scattered throughout the country there are numerous small water-power developments representing practically every type or design of waterwheel, operating under various conditions. Some of these installations are equipped with all the refinements of engineering practice, while others are nothing more than crude makeshifts.

Considered from the standpoint of efficiency in power production about 90 per cent. of these plants show one serious fault—a fault not easily corrected in existing installations, though easily obviated at the time of installation. This is "water reaction" in the wheelpit under the turbine, which may decrease the hydraulic efficiency to a marked extent. In many cases the trouble is caused by not allowing a sufficient depth of dead water directly under the draft tube of the wheel, or it may be caused by the inadequate size of the wheelpit or tailrace.

To secure the maximum efficiency from a waterwheel, it is necessary that the flow of water from the draft tube and through the tailrace should be slow and quiet, somewhat as shown in Fig 1. The water level in the wheelpit should also be at practically the same point of elevation as the tail water of the stream into which it discharges. A loss of even a few inches head in the tailrace may seriously affect the power of a low-head development. Frequently, the utmost care is used to conserve all the available head above the wheel and then a serious loss is allowed to occur in the tailrace or wheelpit.

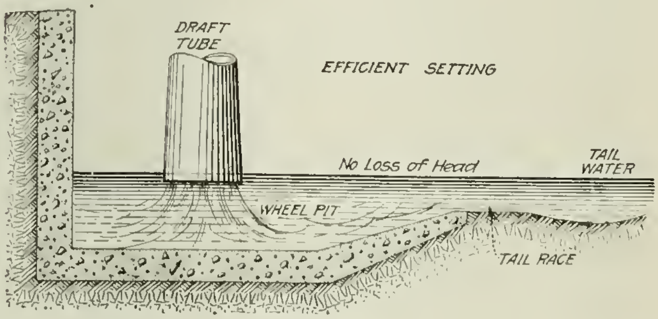

FIG. 1. CORRECT DESIGN FOR TAILRACE

Some months ago a small hydro-electric plant was tested to determine what had caused a marked decrease in the available power. The head was eleven feet and the wheel was supposed to develop about 150 hp., but at the time of the test the maximum output was only about 100 horsepower.

After some investigation it was found that a recent flood had partly filled the wheel pit with gravel and had so choked the tailrace that eighteen inches of the original head was lost. In this case the remedy was easy, for it was only necessary to clean out the gravel to the bedrock in order to secure normal power. However, in many small plants the original excavation has not been carried to a proper depth, as in Fig. 2, and the water is choked at the end of the draft tube and boils forth like a small geyser, dissipating in this watery ebullition much of the energy which should be given to the wheel and turned to practical purposes.

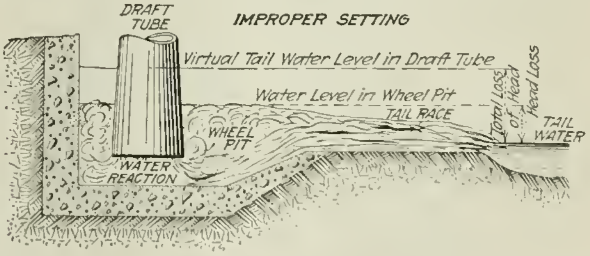

FIG. 2. TAILRACE TOO SHALLOW AND SMALL

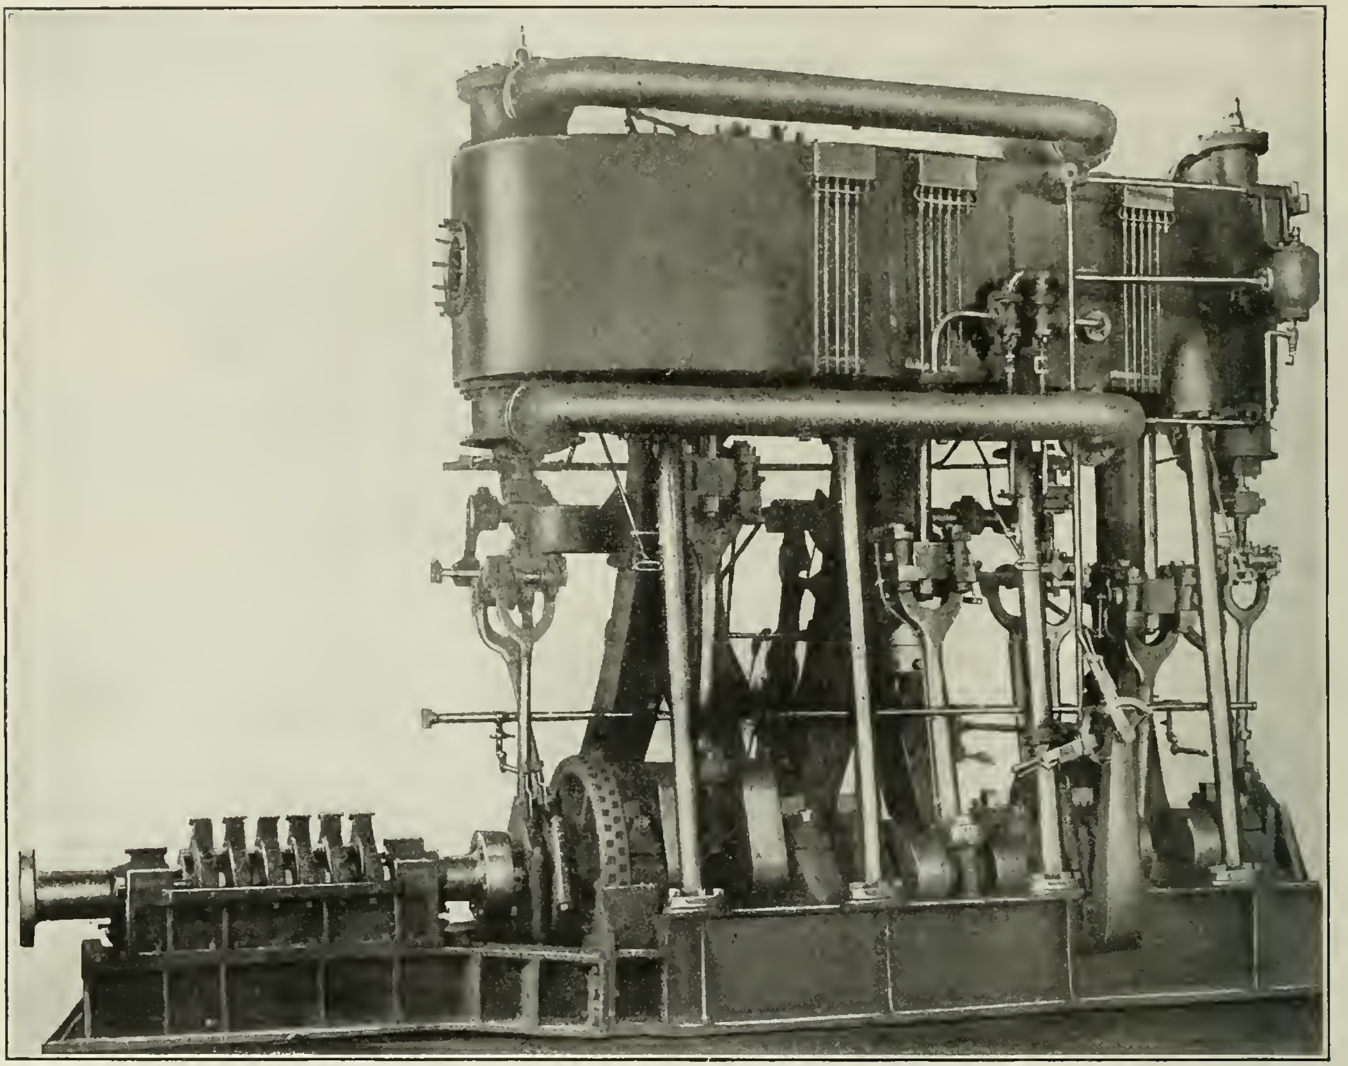
At this particular time, when all the water power is urgently needed to save coal, it is of vital importance that efficiency investigations be made for the purpose of determining how to increase power production and that corrections be applied where possible. Some slight changes in the wheelpit or tailrace at little expense may add considerably to the output of the plant.

Emergency Fleet Engines



THE attack of German submarines on the shipping of the allied and neutral countries has resulted in the sinking of a large number of cargo steamers, the lost tonnage of which must be made good. Because of these losses and the advisability of getting the greatest efficient movement from the available tonnage, the United States Shipping Board has complete charge of all the merchant ships afloat flying the American flag.

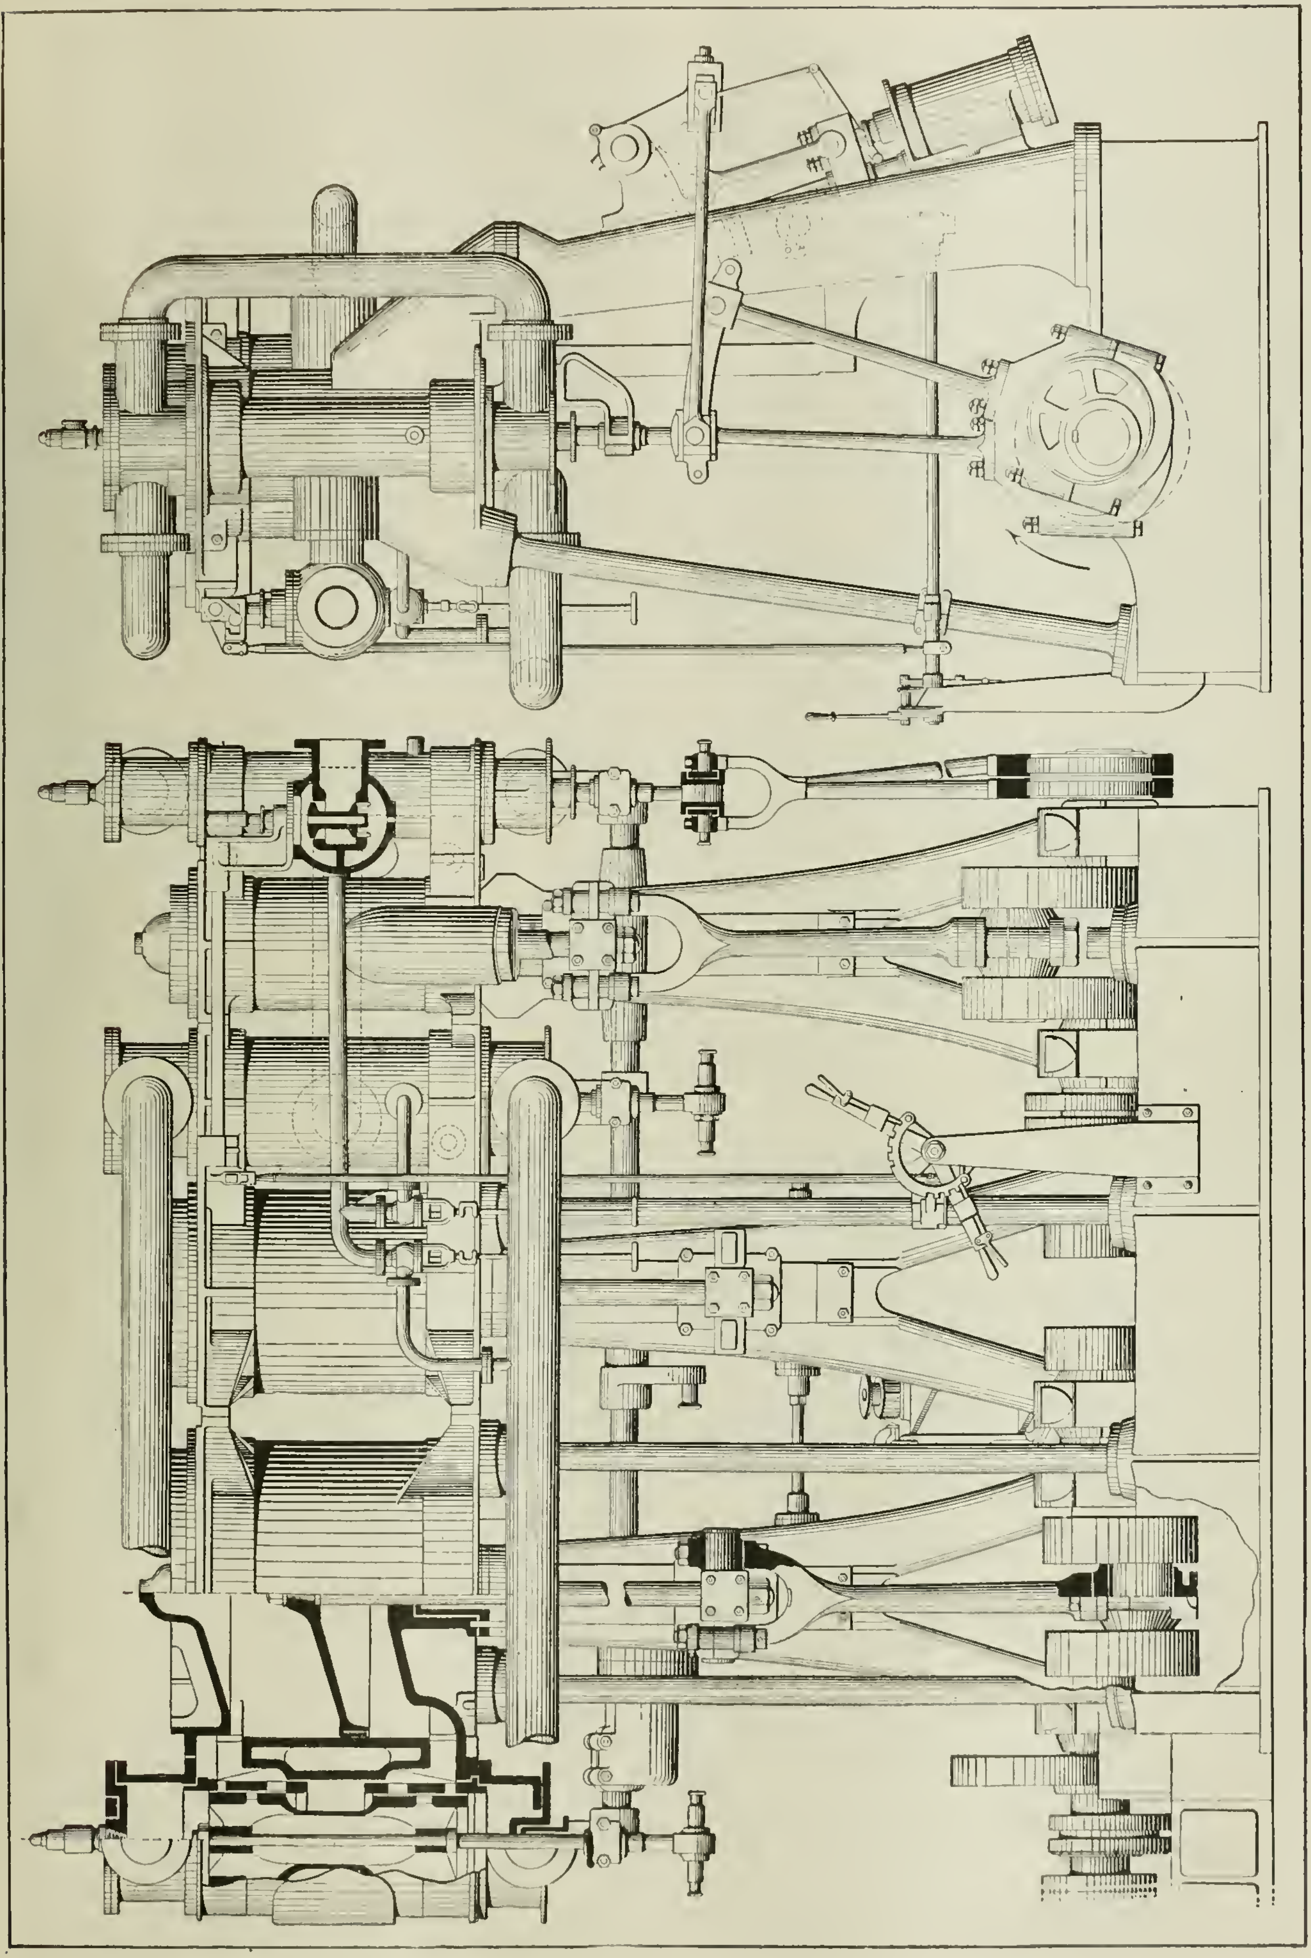
The American Fleet Corporation is a subsidiary of the United States Shipping Board, and its duty is to build ships. As a result of the Shipping Board activities, it has the supervision of the output of more than 150 shipyards throughout the United States, which are all engaged in the greatest shipbuilding program that any nation has ever undertaken. Some of the ships laid down in these yards are completed, others are nearing completion, and the next few months will bring about the launching of a large number of merchant ships that will be engaged in carrying supplies for our own and our allied soldiers. As a matter of fact, under direction of the Shipping Board there have already been launched something like 236 steel and wooden vessels, with aggregate tonnage of 1,440,627. There are now operating 157 shipyards with 753 ways in use, with a predicted launching of four ships per day.

Engineers are interested in the general type of engine that is to be used in these ships that are being built. One of the fore and aft triple-expansion engines, built by the Buckeye Engine Co., Salem, illustrated herewith, shows the general arrangement, the line cut showing a front and end view. It is of 700 hp. capacity and has a $15\frac{1}{2}$-in. diameter high-pressure cylinder, a 26-in. intermediate and a 44-in. low-pressure cylinder. The stroke is 26 in. Piston valves are to be used on all cylinders and are $7\frac{1}{16}$, $14\frac{1}{16}$ and 15 in. in diameter respectively, and are 3 ft. $\frac{15}{16}$ in. long.

The columns on which the cylinders are secured are 7 ft. 1 in. high and are 7 ft. wide at the base. The frame consists of a front and back column, as shown in Fig. 2. This front column is $4\frac{1}{2}$ in. in diameter and the back column is an A-shaped form when looked at from the forward end. These columns carry the guide bars.

As is common practice, the crank rod and eccentric rod are made with the well-known type of boxes. The crankpins are $8\frac{1}{2}$ in. and the wristpins $4\frac{1}{2}$ in. in diameter. The shaft is $8\frac{3}{8}$ in. in diameter. and the cranks are placed at 120 deg. apart.

Two engines, port and starboard, will be the equipment of each ship in most instances in which these engines are placed.



SHOWING THE GENERAL ARRANGEMENT OF THE EMERGENCY FLEET FORE AND AFT TRIPLE-EXPANSION ENGINES

The Electrical Study Course—Characteristic Curves of Compound Generators

The voltage characteristics of compound generators under varying loads, the method of adjusting the series windings to obtain the correct amount of compounding, also the long-shunt and short-shunt connections, are discussed.

WITH a series winding on the polepieces along with a shunt winding, as in the compound generators, Fig. 3, the load-voltage curve will to a certain extent be a combination of the shunt characteristic curve, Fig. 2, and the series curve, Fig. 8, in the previous lesson, issue of May 21. In the compound-connected machine, Fig. 3, current is flowing through the shunt-field winding only, and this is adjusted by the field rheostat to give normal voltage at the armature terminals. When a load is connected to the machine, as in Fig. 4, the current passing through the armature will tend to cause the voltage at the brushes to decrease, but the total-load current flowing through the series winding will increase the strength of the magnetic field and cause a greater voltage to be produced to compensate for the drop in the armature and series-field winding. If we assume that the machine is normally generating 110 volts at no load, the density of the magnetic circuit would correspond to point *A* on the magnetization curve, Fig. 1. When the machine is carrying full load, if the current flowing in the series-field winding increases. the magnetic density to correspond to point *B* on the curve, then the armature will be generating about 124 volts; that is, the voltage generated in the armature has increased from 110 to 124, or 14 volts. Now, if the volts drop in the armature, from no load to full-load, is only 14, then the volts at the armature terminals at full load will be the same as at no load.

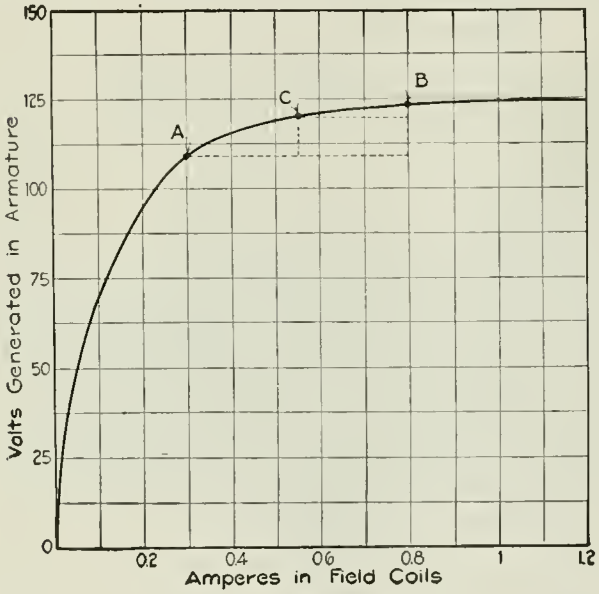


FIG. 1. DIRECT-CURRENT GENERATOR VOLTAGE CURVE

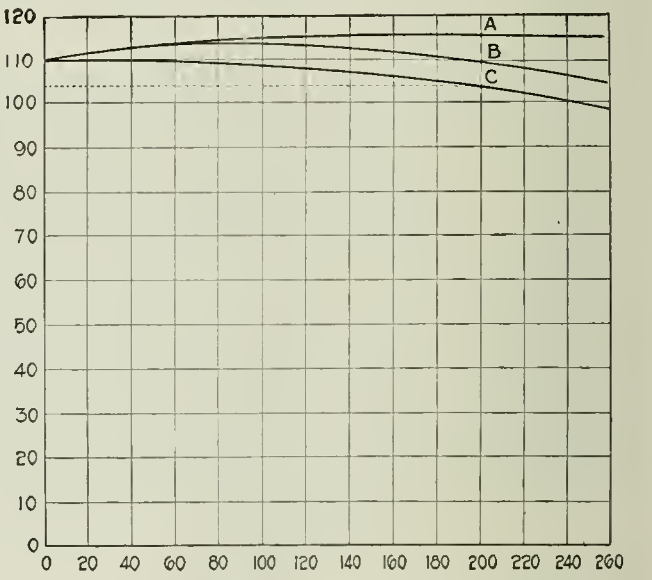

FIG. 2. COMPOUND-GENERATOR LOAD-VOLTAGE CURVE

At first thought it may seem an easy matter to proportion the series-field winding so that it will just compensate for the drop in the armature circuit. A further consideration of the curve, Fig. 1, will show that this is impossible. If point *A* indicates the no-load voltage and point *B* the volts generated in the armature at full load, point *C*, half-way between *A* and *B*, will indicate the volts at half load. But from *A* to *C* the voltage has increased from 110 to 120, whereas from *B* to *C* it has only increased from 120 to 124, or 4 volts, against 10 on the first half of the load. The volts drop in the armature is proportional to the amperes, consequently if full-load current causes a drop of 14 volts, then half full-load current will cause 7 volts drop. But with half full-load current flowing in the series-field winding, in this case, it caused 10 volts increase, therefore, the voltage at the brushes is 3 volts higher than at no load What has really happened to the voltage of the compound generator from no load to full load is indicated in curve *B*, Fig. 2, assuming 200 amperes full load. Here it is shown that although the voltage is the same at full load as at no load, nevertheless, it has not been constant between these points, increasing in value during the first half of the load and then decreasing to normal again during the last half. Furthermore, it is not possible to design a compound generator that has a constant voltage from no load to full load. However, conditions similar to that indicated by curve *B*, Fig. 2, can be approximated.

A compound generator that develops the same voltage at full load as at no load is said to be flat-compounded. It is possible, by proportioning the shunt- and series-field winding, to design a compound machine where the voltage will increase from no load to full load, as indicated by curve *A*, Fig. 2. For example, we assume that the full-load current causes 14 volts drop in the armature. Now, if the current flowing through the series-field winding caused a 20-volt increase in the armature, then the voltage at the armature terminals will be 20 — 14 = 6 volts higher at full load than at no load. When the voltage of a compound generator increases from no load to full load, the machine is said to be over-compounded.

On the other hand, suppose that when full-load current is flowing in the series-field winding it caused only 8 volts increase; then, since there is 14-volts drop in the windings at full load and only eight of these volts are compensated for, the pressure will decrease at the brushes, 14 — 8 = 6 volts. Such a condition is represented by curve *C*, Fig. 2. A compound generator the voltage of which decreases from no load to full load is known as being under-compounded.

Another feature in obtaining the proper amount of compounding of the generator is the proper number of turns in the series winding. This winding in the large-sized machine is made of a heavy copper bar, as in Fig. 5, therefore, the terminals will have to come out on opposite sides, so that the connection can be made conveniently between the coils. This means that the minimum number of turns in the coil must be 1.5. Then, to maintain the proper position of the coil's terminals the number of turns will have to be 1.5, 2.5, 3.5, etc. One-half turn in the series-field winding at first thought may not seem to be of any serious importance. However, when it is considered that in a 200-kw. 110-volt machine the normal full-load current is approximately 2000 amperes, and this current flowing through one-half turn gives 1000 ampere-turns, the effect that only a small fraction of a turn in the series winding will have upon the voltage of such a machine at once becomes apparent.

Here again, in the design of the series winding, it is impossible, except by a coincidence, that the correct number of turns can be obtained. The result is that as the series-field winding is designed on most compound generators, the machine is over-compounded.

For example, assume that in working out the design of a machine it is found to give the proper amount of compounding, that 3.8 turns will be required in the series winding In this the designer has the choice of using only 3.5 turns and having the machine slightly under-compounded, or using 4.5 turns and over-compounding the machine. The latter is the best course for several reasons. Due to imperfections in the materials and workmanship, the machine may vary somewhat from what was expected of it. In fact, it is practically impossible to build two machines after the same design and from the same lot of stock and have them both possess the same characteristics. Therefore, it is good policy to use a liberal design in the series-field winding, since there is a simple means for adjusting the ampere-turns of this winding when the machine is over-compounded. This consists of connecting what is known as a compounding shunt directly across the series-winding terminals, as shown in Fig. 6.

After the machine is built and in operation in the shop, a test is made to find out the amount of resistance that must be connected across the series-field terminals to give the required compounding, and then a shunt is made for this purpose and connected to the terminals of the series winding. Then, instead of all the load current passing through the series winding, only part of it does, depending upon the resistance of the shunt. If the full-load current of the machine is 1000 amperes and only 800 amperes are required to compensate for the volts drop in the series and armature windings, at full load, then the shunt is made to have a resistance four times as great as that of the series winding, so that when it is connected in parallel with the series winding one part of the current will pass through the shunt and four parts through the series winding, or any degree of over-compounding may be obtained up to the maximum by increasing the resistance of the shunt. Direct-current generators have been built for railway work in which the voltage increased from 500 at no load to 550 at full load, this increase in voltage being

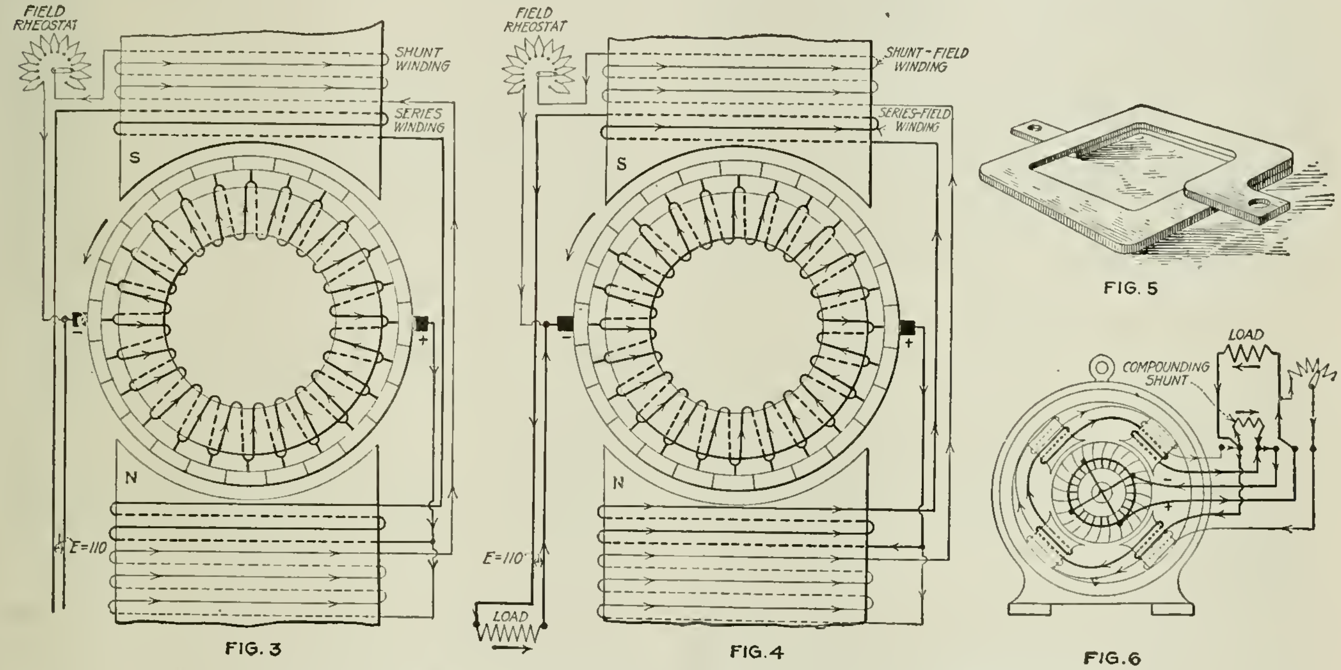

FIG. 3 FIG. 4 FIG. 5 FIG. 6

FIGS. 3 TO 6. COMPOUND-GENERATOR CONNECTIONS AND SERIES-FIELD COIL

Fig. 3—Diagram of Compound Generator. Fig. 4—Diagram of Compound Generator Connected to Load. Fig. 5—Large-Capacity Series-Field Coil. Fig. 6—Compound Generator Showing Location of Compounding Shunt

used to compensate for the volts drop in the feeders.

In passing, attention may be called to the way that the shunt-field windings are connected. In Figs. 3 and 4 the shunt winding is connected directly to the armature terminals. This is known as a short-shunt connection. In Fig. 6 the shunt winding is connected directly across the series winding and armature in series, so that in this case the shunt-field current passes through the series winding also. This is known as a long-shunt connection. Since the shunt-field current is only a very small percentage of the total load of the machine, it is evident that it makes little difference which connection is used, the choice being more a matter of convenience than anything else.

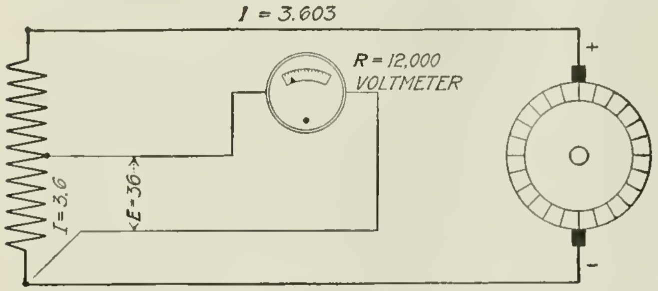

FIG. 7. VOLTMETER CONNECTED ACROSS SECTION OF RESISTANCE

Fig. 7 gives the layout of the first problem in the last lesson. This problem is solved by Ohm's law. The current flowing through a voltmeter is in all cases equal to the volts impressed across its terminals divided by its resistance, or in this case equals $36 \div 12{,}000 = 0.003$ ampere. The resistance of the section of the circuit that the voltmeter is connected across is equal to the volts drop across the section (the voltmeter reading), divided by the current, or $36 \div 3.6 = 10$ ohms. The total current in the remaining part of the circuit will be that taken by the voltmeter and that flowing in the section the voltmeter connects to, or $0.003 + 3.6 = 3.603$ amperes.

The second problem was, if the resistance of a voltmeter is 15,000 ohms and when connected across a given circuit 0.01 ampere flows through it, does the instrument indicate the correct voltage of the circuit if the needle points to 140 on the scale?

In all cases the correct reading of a voltmeter is equal to the resistance of the instrument times the current passing through it, in this problem, $15{,}000 \times 0.01 = 150$ volts. In this case the instrument reads 140; therefore. it is indicating $150 - 140 = 10$ volts low.

A given compound generator develops 125 volts at no load, the armature and its external connection has 0.075 ohm resistance, the series field winding 0.045 ohm. Neglecting the effect of the load upon the shunt field, what will be the voltage across the armature terminals at a 150-ampere load, also across the line terminals, if the load current of 150 amperes through the series winding causes the armature to generate 20 volts more than at no load?

A Day With the Refrigerating Troubleman

By E. W. MILLER

The troubleman takes the reader along on two hurry calls for help from plants where the refrigerating machines refuse to properly perform the work.

A REFRIGERATING plant of 15 tons capacity had been installed in a large department store. The equipment for the building was electrically driven, and the heat was supplied from an adjoining building; so the plant was operated by the electricians. After the refrigerating plant was installed, a man was left with the chief electrician for a short while.

A month after the man had left, we received a rush order from the chief electrician to come at once; the crankshaft of the machine had been broken. It was plainly not a case of defective material. I asked the chief electrician what had taken place, and he appeared to be as much in the dark as I about it. He said he was out of the engine room at the time of the accident and when he came in the belt was on the floor and the machine had stopped.

I was unable to find anything wrong, and to keep peace in the family we sent out another crankshaft. This was in the latter part of February. About the middle of April we received another complaint from this plant. I was sent out again, and this time the electrician informed me that he could not maintain the required temperatures in the various rooms.

I first turned my attention to the compressor, with which, of course, I was thoroughly familiar. Judging from the sound of the valves, the load indicated by the wattmeter and the suction and discharge pressures, I was sure that the compressor was not to blame.

The compressor was running very hot; the suction line was bare, and there was not a sign of frost as far back as where the line passed out through the wall to the coolers. The condenser pressure was lower than I would expect for the temperature and speed of the compressor, and the suction pressure was also low for the temperatures carried in the coolers, which were liberally piped.

On entering the cooler room, I found that the coils were only slightly frosted; the sharp frost line that is always present on an expansion valve that is working properly was missing, and the liquid line leading to the valves was warm—considerably warmer than it should be according to the water temperature and the head pressure carried.

Everything pointed to a shortage of ammonia. The problem was to account for its disappearance, as we had provided a liberal charge when the plant was started. The electrician said there had been no blowouts and he had never detected a leak except at the stuffing-box.

The entire system was pumped down to vacuum, after which I cut in the coils one at a time. In this way one could determine just about what proportion of the ammonia had been lost by seeing how many coils could be operated with the ammonia on hand.

Expansion cocks had been provided instead of valves. When I opened the first one, after pumping down, I was surprised that there was no sound of liquid passing the valve. There was no sign of frost on the valve. Always, after pumping down in this way the expansion valve will frost at once it is opened. This coil was entirely dry and had evidently not been used. Upon inquiry the chief informed me that it had not been in service since the plant had been started. This led to further investigations, and I had a hunch where all the ammonia had gone to. The suction valve was shut.

COIL FULL OF LIQUID

I casually asked the chief if he had ever had this coil in service and if so, for how long. This brought forth the information for which I had been looking: He said that he had cut it in on the day he found the crankshaft broken and had shut it off again and had not used it since.

I had him get one of the men to open the valve slowly after we were back in the engine room. I then partly closed the suction stop valve on the machine and awaited developments. There was a succession of thumps in the machine, and the belt nearly came off and screeched as it slipped on the pulleys. I gave the suction stop valve a spin that sent it shut at once and the racket stopped as suddenly as it had started. The thumps were so severe that it jarred the floor of the engine room and made the pipes connected to the compressor dance in the hangers; two of the joints started to leak.

It was then explained to him that this was what happened when he had opened up this coil at the time the crankshaft had broken; that the coil evidently was full of liquid, that he likely opened the valve quite lively and sent a slug of liquid of large volume into the suction line, the shock twisting off the shaft.

The suction stop valve was then gradually opened until the entire mass had been worked through the compressor. The system was pumped out and the bonnet removed from the expansion cock of the coil that had caused the trouble. Here I found that a piece was broken out large enough so that when the valve was closed as far as it would go, it would not quite shut off the flow to the coil. A new cock was put in and the plant started. It went along splendidly and did the work easily.

SUCTION VALVE SHOULD HAVE BEEN OPEN

The leaking cock had allowed the coil to gradually fill with liquid ammonia. The weather was cold at first, and sufficient ammonia was left in the rest of the system to keep the temperatures down until the weather became warmer. When he had attempted to open the valve and cut in the coil at the time the crankshaft broke, the large amount of liquid had, as stated before, rushed into the suction line and back to the compressor, causing the accident. He had then shut off the valve, and the coil had gradually filled again, removing a large portion of the ammonia from the active part of the system, and when the weather warmed up there was not enough to do the work. If the suction valve had been left open all the time, as it should have been, none of this trouble would have happened and the leaking expansion cock would have been detected in a short time by the inability to close it tightly.

In another case a 25-ton plant had been installed in a hotel. About two months later we received a call to come and "straighten out the plant," as it refused to work. Arriving, I was informed by the engineer that the cooler temperatures were "scooting up," the compressor was ice-cold, the suction pressure was down below atmosphere, and the expansion valves were barely cracked open.

Cooling was done by brine circulated from the engine room. A triple-pipe brine cooler was used, and a centrifugal pump circulated it. At first I could discover nothing wrong. The brine pump was spinning along merrily, and to all appearances everything was working nicely. The temperature of the brine as it left the cooler was much higher than usual, and judging from this in connection with the low suction pressure and the cold machine, it looked as though the cooler was not doing the work.

Thermometers in the inlet and outlet of the cooler showed the temperatures were about the same. Evidently the cooler was out of commission. I opened one of the drain valves at the bottom of one of the coils to see if there was any circulation; nothing came out. I removed one of the return bends and found ice. The rest of the coils were more or less in the same condition.

THAWING OUT THE COOLER

The machine and pump were shut down and a steam hose used to thaw the ice. Burlap and bags were used to wrap the cooler and hot water from the feed-water heater run over it. This thawed it out rapidly. All the return bends were removed; heated rods driven into the center pipes.

When I thought most of the brine was out, I opened up the valves in the inlet between the cooler and the pump and also the suction valve to the latter, intending to utilize the head on the pump to force out the remainder of the ice in the bottom pipes. To my surprise nothing happened. I ran the rod clean through the pipe, and a little brine trickled out.

Opening the pet-cock on the top of the pump showed there was no pressure on it. But brine flowed freely from a drain valve on the other side of the suction stop valve. Evidently there was something wrong with the suction stop valve to the pump. On removing the bonnet from this, we found that it had dropped the gate; remained closed, and as there then was no circulation through the brine cooler, the brine froze. As soon as the cooler was frozen, there was nothing to boil the ammonia, and it came back to the machine and froze it; the suction pressure, of course, also came down, as there was no ammonia evaporated.

To prevent further recurrence of the trouble, another thermometer was provided for the inlet to the cooler and the temperatures read every half-hour. If this had been done before, the trouble would have been noticed before the cooler froze and an investigation would have located the trouble before any damage had been done.

Stets Boiler-Feed Controller

The function of a controlling element on a boiler feed-water line is to maintain the water level in the boiler at a predetermined height and to do so by maintaining a continuous flow of water to the boilers. Numerous designs of regulators have been devised of both the float and the thermostatic-control type. The more simply a feed-water regulator is constructed the less likely it is to get out of order and the more dependable it will be. It has been difficult to make the float of the float-controlled regulator strong enough to withstand the high steam pressure now carried and at the same time buoyant and powerful enough to operate the controlling valve.

The design of the water-controlling valve is also an important matter, and the proper type of valve seems to have been adopted in the new Stets boiler-feed controller, which is manufactured by the Williams Gauge Co., Pittsburgh, Penn. This controller is self-contained, and the float-control principle is used. It is made of two types, as shown in Figs. 1 and 3.

The controller, Fig. 1, consists of a horizontally split casing containing a copper float which actuates the feed valve by means of a lever, as shown. As the working parts are all in the pressure space, stuffing-boxes have been omitted. The float and the control valve are the interesting features of the controller.

The copper float is heavy enough to withstand a cold-water pressure of five times the working pressure. When the boiler is in service, the upper half of the float is surrounded by steam of a temperature corresponding to the pressure of the steam in the boiler, but the lower half is surrounded by water that does not have a temperature equal to the pressure. Therefore, the temperature inside the float is a mean between that of the steam above and of the water below the floating line of the float. As the float contains a certain amount of volatile liquid having a boiling point lower than that of water, it vaporizes at the mean temperature existing inside the float and builds up a pressure approximately equal to the boiler pressure on the outside of the float.

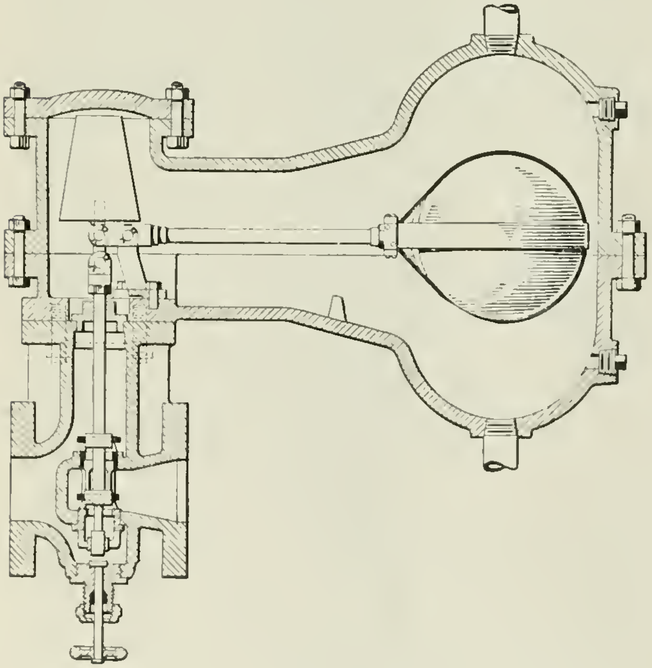

FIG. 1. SECTION THROUGH TYPE-A CONTROLLER

A balanced piston type of valve is used, both pistons being of the same diameter. This piston fits in a sleeve in which there are four V-shaped ports near its upper and lower ends. The central portion of the sleeve has three large openings, the area of which is considerably in excess of that of the upper V-ports. As the lower end of the valve sleeve only is threaded to its seat, it can be withdrawn without disturbing the valve or breaking any of the pipe connections.

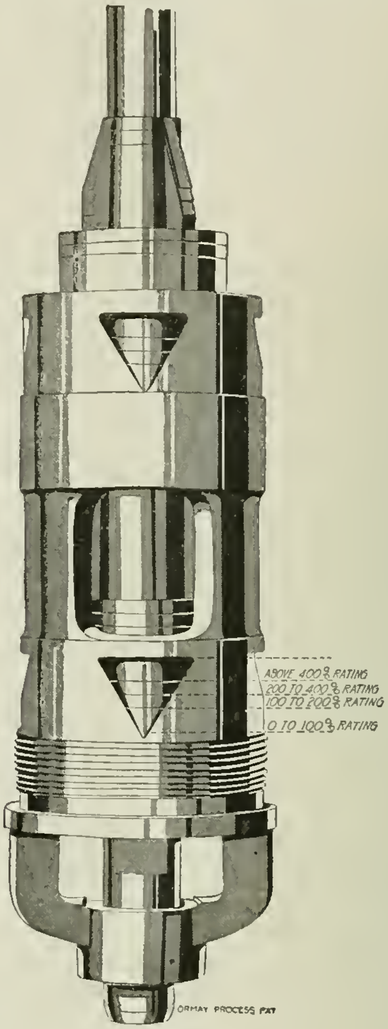

FIG. 2. DETAILS OF THE VALVE

The valve does not seat, but is designed to control a continuous flow of water through the V-ports. Fig. 2 shows the piston disks in three positions and gives a general idea of the different degrees of valve opening required to feed a boiler at the rating indicated and with a normal excess pressure on the inlet side. About $\frac{5}{16}$-in. lift takes care of the feed requirements for usual loads.

The movement of the valve stem is directly proportional to the movement of the water in which the float rides, but the flow of water through the ports is proportional to the amount that they are uncovered by the piston.

The controller shown in Fig. 3 operates on the same principle as that shown in Fig. 1. The casing, however, instead of being split horizontally, is provided with two top openings through which the float lever and counterweight are placed in position. Instead of putting the counterweight on top of the valve stem, as shown in Fig. 1, a housing is provided on the end of the controller casing and the counterweight is placed in a horizontal position instead of in a vertical one. This casing is designed for high pressures up to 350 lb. and for the higher pressures is constructed of cast steel. The casing shown in Fig. 1 is for pressures up to 250 lb. and is made of cast iron.

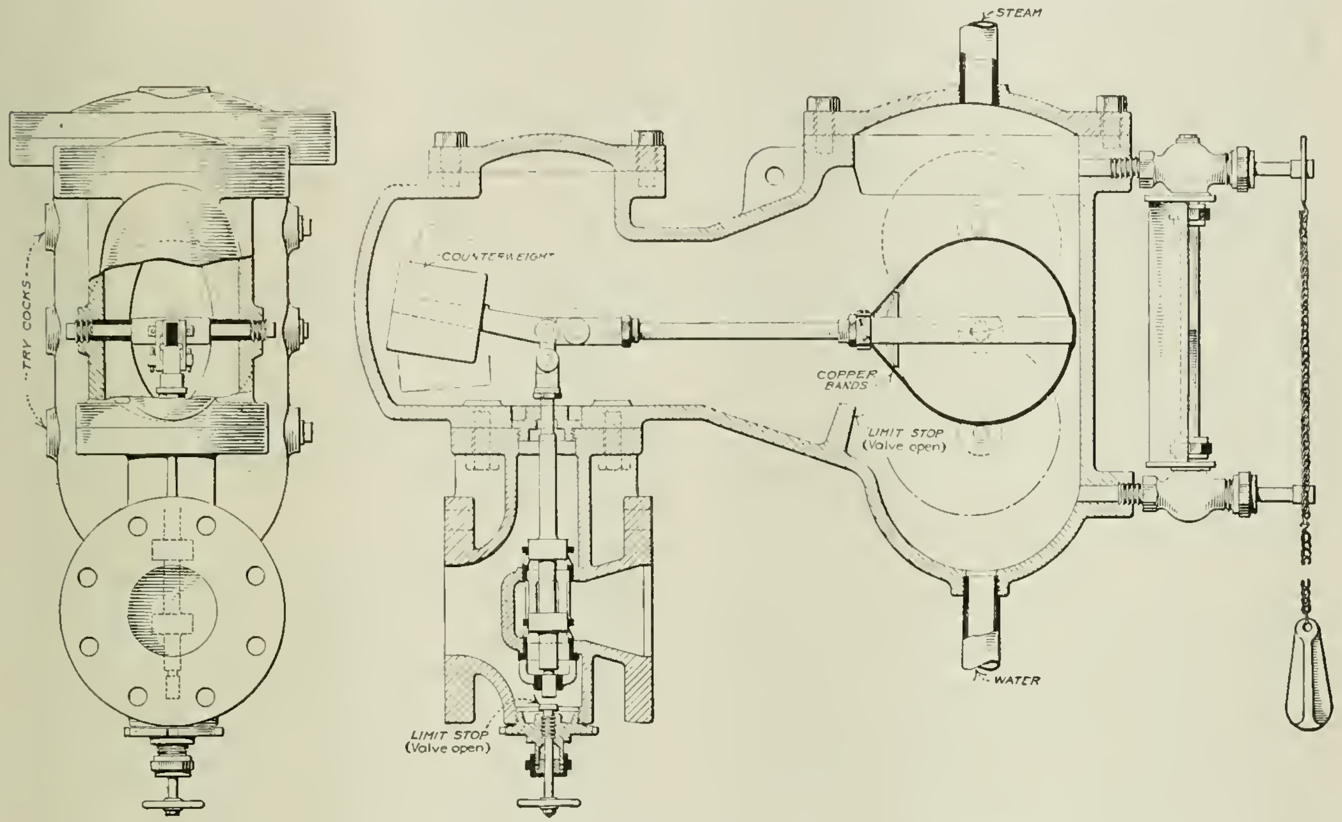

FIG. 3 END VIEW AND SECTION THROUGH TYPE-B CONTROLLER

The controller may be set at the corner of the boiler setting and connected to the boiler with the usual steam and water piping. The controller shown in Fig. 1 is used in conjunction with a water column; that shown in Fig. 3 is in itself a water column and is fitted with the usual try-cocks and gage-glass.

Atmospheric Vapor-Absorption System

By G. C. Derry

In a power plant at Port Henry, N. Y., on the shores of Lake Champlain, a troublesome vapor condition existed in cold weather from cold air coming in and condensing the moisture in the warm air in the boiler room, which caused a fog so dense that the firemen could scarcely see their steam gages and water glasses from the floor of the boiler room. Several plans for getting rid of the vapor were tried without success. The coal supply was just outside the boiler room, and there was a continual opening and closing of doors as the firemen brought the coal in. The fog was so dense, in fact, that when the firemen started in with the coal, they had to shout in order to avoid running into each other, and it was difficult to get men to stay and work under such conditions. Water tenders had to be put on in order to watch the water gages from an elevated platform constructed in front of the boilers.

A condition existed which resembled the blowing of one's breath into cold air in the winter time, and it seemed to me that the logical thing to do was to bring the incoming air up to the temperature of the room or possibly a little higher, so it could carry off some of the vapor. Proceeding along these lines, a large heater and multivane fan were installed, which drew the air from the room, mixed it with some fresh air from outside and forced it through a duct system leading along the sides of the room and down each side of each door and up against the cold surface of the windows. The fan and heater were installed on an inclosed platform over the door which led to the coal pile, and advantage was taken of this platform—making it a ceiling of a room into which to pour a large amount of heated air.

The fan had a capacity of 33,000 cu.ft. of air per minute, and the air in the room was changed every three minutes. The heater was capable of heating this amount of air from 10 deg. to 158 deg. when supplied with steam at 60 lb. pressure. The system had the advantage of removing the steam in the winter and also providing a means of ventilation in the summer.

The owner has advised us that the system worked satisfactorily, removing every trace of the vapor even during the extremely cold weather last winter.

Most engineers would have a fit if cast-iron nuts were furnished for the valve chest and cylinder covers, yet one end of these studs is always in a cast-iron nut. But on that account there are no fits, showing that it makes a mental difference which end of the stud you are thinking about.—*Marine Engineering.*

Not because he loves cast iron less, but steel more.

Conditions in the Power Industry

BY LUDWIG W. SCHMIDT

A digest of the reports of the United States consuls on the power situation in the various parts of the world and the influence of the war upon this important industry. Also, see "Power," March 5, 1918.

THE electrical power development of the world outside the United States has been influenced by two distinct factors during the last three months. One has been the increasing demand for electrical power and the other the lack of funds to make the urgently needed extensions. As a result, most of the existing central stations report increased business and all say that they could do more if they had the necessary installation.

In Europe, where the immediate needs seem to have been largest, extensions have been made where urgently wanted so as not to cripple the activity of the national industries. Outside Europe, however, development has been held back, and there is plenty of evidence that many projects which should have been carried out during the present year have been deferred to a later time. Central stations in all parts of the world report that they have difficulty in making contracts for additional equipment and that where it has been possible to place the orders the contractors remain behind with their deliveries.

Norway seems to be an exception to the rule. The expansion of hydro-electric enterprise which has been characteristic of the economic life of that country during the last year continues during the present. Commercial Attaché Erwin W. Thompson writes from Copenhagen (C. R. 1.)[1], that it is proposed to develop 100,000 hp. from the Gaudefaldene waterfalls near Stavanger. The power to be obtained will be used principally for the production of carbide and for other electrochemical industries. To provide for the labor essential to the new industries it is intended to build a village near the falls.

UTILIZING WATER POWER FOR SMELTING IRON ORE

The same consul reports a scheme to utilize water power for the smelting of iron ore. Norway has large iron-ore fields which yield more iron than can be used in the country. This ore at the present time is exported to be smelted, but it is thought feasible to smelt it in the country. The beginning will be made with ore produced in the Braastad mines, near which 2500 hp. can be created (C. R. 3). As there is a lack of hydraulic and electrical machinery, it is expected that large quantities will have to be imported. Electrical smelting also will be resorted to in a new steel mill which is to be built in Risor, near Christiania. This mill is expected to turn out from 30,000 to 40,000 tons of steel every year. The power for smelting will be taken from the Hoge Falls, where from 150,000 to 200,000 hp. can be obtained. Only 22,000 hp. will be needed for the beginning (C. R. 64).

If the utilization of hydro-electric power for smelting should become more general in Norway, it is certain that this country will be in need of much machinery which, for a while at least, she most likely will buy either from England or from this country. The machinery for the Gaudefaldene scheme is to be supplied by England.

Most of the Norwegian electrochemical enterprises seem to have been operated with considerable success during the last year. The annual report of the Norsk Hydro, which controls 300,000 hp. and has a capital of $15,450,000, shows that this company has increased its net profit from $4,900,000 during 1916 to $6,650,000 during 1917. The business year covered by the report runs from July to June for each year (C. R. 33).

ENGLAND MAKING PREPARATIONS FOR POST-WAR DEVELOPMENT

In England all electrical-power development at present is influenced by the preparations made for the reorganization of all power supply which is expected to follow the war. With the possibility that great changes will be made in the production and distribution of power, local enterprises show little inclination to invest in new installations. Only the most urgent additions are made. New installation work is also hampered a good deal by lack of labor and materials which are needed more urgently somewhere else.

In the meantime the local power and traction companies are doing good business. The Glasgow Corporation tramways, for instance, have to report an increase in takings of $391,618 for the period from June 1 to Nov. 30, 1917, in comparison with the same period of 1916. During the six months of 1917, 212,961,987 passengers were carried as against only 192,399,712 in 1916 (C. R. 4). No new enterprises of any extent are reported, but Consul J. S. Armstrong, Jr., writes from Bristol that the municipal authorities will be compelled to extend the local electrical plant by installing a 6000-kw. turbo-alternator, four water-tube boilers and switch gear. The additional installation is made necessary by the increased demand for electrical power.

LACK OF ELECTRICAL ENGINEERS IN SPAIN

During the last year Spain has had a fair share of the so-called war prosperity, which in many cases has made necessary additions to the existing generating stations. It seems to be generally realized that that country in the future will have to rely more than ever on its own industrial resources, which in turn will necessitate the provision of better electrical-power facilities than heretofore. So far there has been a lack of sufficiently trained Spanish electrical engineers. This deficiency will now be eliminated by giving increased opportunities for the study of electrical engineering. The City of Barcelona therefore has added a special Institute of Electrical Industries to the Industrial School of that city, the influence of which should very soon be felt in the electrical industry of the country (C. R. 11).

Italy has made good use of its great hydro-electric possibilities during the war. Consul Joseph E. Haven in Turin points out in this respect that many factories in Italy which formerly were operated by steam power are now using electrical power and that electricity has

---

[1] C. R. indicates "Commerce Reports" of 1918.

become the standard motive force. This change has been made possible by the erection of big electrical central stations, which in some instances supply power over distances of hundreds of miles. Before the war Germany supplied most of the electrical-power machinery in use in Italy. Since Italy entered the war, connection with Germany, of course, has been broken off, and now American, English and Swiss machinery is used in preference. Also the Italian electrical industry has made considerable progress (S. C. R., Feb. 8, 1918).[2]

The industrial census of Africa for the year 1915-16 has shown again the great progress made in the use of electrical power in that country. There were in South Africa proper 1214 establishments using electrical power to the extent of 121,229 hp., as against only 689 using 564,664 hp. generated by steam, 440 using 5985 hp. generated by oil engines, 181 using 6266 hp. generated by gas and 152 using 3759 hp. generated by water. In the Transvaal 430 establishments used 84,634 hp. generated by electricity and 226 used 294,956 hp. generated by steam (C. R. 6).

ELECTRICAL POWER INDUSTRY IN SOUTH AMERICA

The last year has brought much activity to the electrical power industry of South America. Many new industries have sprung up to supply those articles which the South American countries cannot buy any longer from Europe owing to the war, and these industries had to be supplied with cheap and reliable power. So an increased use has been made of electricity. In Venezuela an attempt will be made to use one of the waterfalls in proximity to Caracas. Consul Homer Brett in La Guaira says that this development will be carried out by American capital. The water power to be used is that of Naiguata Falls, which have a drop of 3373 ft., and it is expected that 8000 hp. will be created from this source. The necessary investment will amount to approximately $1,000,000, which will be obtained with the assistance of American banks (C. R. 6).

State ownership of electrical enterprises has advanced another step in Uruguay, where the government just now has acquired its sixth electrical power plant. The station in question is that of Mercedes, which was the property of the firm of Preve y Hermanos. The government also owns electrical central stations in Montevideo, Colonia, Canelones, Maldonado and Pando. All government plants are under the control of the Administracion General de las Usinas Electricas del Estado (C. R. 40).

Consul William Dawson in Montevideo reports in the same connection (C. R. 41) that all the state electrical plants are burning oil fuel, which under a special contract is supplied by the West India Oil Co. Under its agreement with the company the state has the right of preferential treatment as to supplies and has just now made an order that the company keep a reserve of 5000 tons of oil, to be held for use of the government.

Consul Charles L. Latham in Kingston, Jamaica, says that there is a demand in that island for small individual power plants to be installed in country houses. Electrical power so far is available only in the cities. Farmers and planters realize well the great advantages to be derived from the employment of electricity in the operation of farm machinery, the lighting of houses, etc. Power outfits should consist of a kerosene engine, a dynamo mounted on the same shaft preferably, and a bank of storage batteries. The price should be approximately $400 (C. R. 38).

INDUSTRIAL ACTIVITY IN JAPAN AND CHINA

The enormous increase in industrial activity in Japan resulting from the war has caused a great demand for electrical power, which has necessitated the erection of many new power stations. Although there is, strictly speaking, no boom in power development, business nevertheless has been very active and the number of electrical enterprises has increased 50 per cent. There are now 674 electrical stations in Japan having a combined capital of $339,422,119. The combined power supplied by these stations has a daily average of 922,940 kw., of which 700,870 kw. is generated by hydro-electric stations. The remainder is generated mostly by steam. During the last year steam generation has made greater progress than water-power generation. There was a total increase of the average daily power supply of 131,706 kw. (C. R. 36).

The activity in the electrical industry in eastern Asia, however, is not confined to Japan only. From a report by Consul General P. S. Heintzlman in Canton, China, it appears that China has had its share. There has been apparently a good deal of difficulty in securing the supply of electrical-power-station machinery in China during the last three years, which has hampered considerably the development of the industry. The Kwangtung Electric Supply Co., for instance, has contemplated an extension of its power equipment for a long time. It has now been possible to place a contract with a firm of American engineers for the purchase of two American high-pressure condensing turbo-alternators, rated 2500 kw. three-phase 60-cycle 2300-volt; one American high-pressure noncondensing turbo-generator, 35 kw. 125-volt direct-current; and switchboards, pumps and other accessories. The contract also provides for four 750-hp. Babcock & Wilcox boilers. In all, $433,500 in gold will be spent for the new equipment.

The Kwangtung Electric Supply Co. is a Chinese enterprise which was established during 1909 with a capital of $480,000, American money. Its monthly takings are now approximately $60,000. The plant has been a success from the start, and will be the second of importance in China after the completion of the extensions now ordered.

CENTRAL STATIONS IN SOUTH CHINA

South China contains a number of electrical central stations. As the most prominent of these the consul mentions the following: Kowkong, Kongmoon, Sainam, Taileung, Sheklung, Chanchuen, Sunning City, Suncheng, Fatshan, Shin Hing, Siulam, Shekki and Kiungchow, all in the Kwangtung Province, and Wuchow and Nanning, in the Kwangsi Province. Most of the electrical equipment of these stations is of American manufacture, though most of the machines were purchased from England. The plant in Sunning City is equipped with Swedish machinery. Most of the stations in question are private enterprises. Those in Fatshan, Sainam, Shin Hing, Nanning and Wuchow are owned by the

---

[2] S. C. R. indicates "Supplement, Commerce Reports."

Chinese government. The motive power is provided practically everywhere with the help of internal-combustion engines. Now experiments are made with native coal, and the new plant in Canton will be the first burning Chinese coal under its boilers (C. R. 4).

The war also has brought much business to the central stations of India. Southern India to-day has three large electric-power companies, says Consul Lucien Memminger, of Madras (C. R. 44). These are at Madras, Bangalore and Hyderabad. So far only one electric railroad is operated in the district of the consulate, which is that in Madras. This is 28 miles long, but the war has made necessary an extension of the system which may be taken in hand very soon. The report tells of several new electric railroad schemes. One of these refers to a line from Kulaskharapatnam to Tiruchendur in South India. This line will have a length of 29 miles and it will be built by an English firm. Electrical expansion in India suffers as anywhere else from the lack of available capital. So it seems that two projects—one to establish railways in Mysore and the other to extend the power station at the Cauvery Falls—both of which have been worked out by S. G. Forbes, an American engineer and chief electrical engineer of the Mysore government, will have to wait. The estimated cost of these undertakings will be $3,147,000. The Mysore power undertaking has just received permission from the government to install an electric-lighting system in Madura. Orders have been placed in the United States for hydro-electric machinery at a value of over $1,000,000 to be used in connection with the Andhra Valley development executed by the Tata Hydro-Electric Power Supply Co.

Evertite Sta-Lok Nut

A nut that is likely to work loose is a source of danger, trouble and anxiety to the user. Numerous devices have been employed to prevent nuts from loosening, some being home-made and others patented. A recent addition to the number is known as the "Sta-Lok" Nut, manufactured by the Evertite Nut Corporation, Detroit, Mich.

This nut will not loosen under heavy stress, nor from violent or prolonged vibration, such as is experienced with some types of high-speed machinery. It looks like any other nut from the outside. On the interior, however, there is a hardened steel ball that runs in a groove between the bolt threads, Fig. 1. This ball is kept in contact with the threads, Fig. 3, by a spring, and when the nut tends to unscrew the spring forces the ball to wedge in the threads, which tightens the nut and so prevents it from working loose.

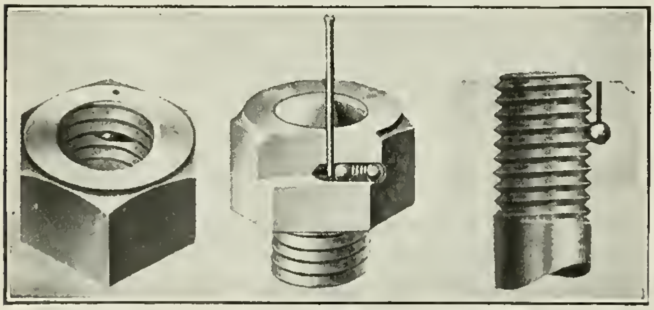

FIG. 1. THE NUT. FIG. 2. UNLOCKING. FIG. 3. LOCKING

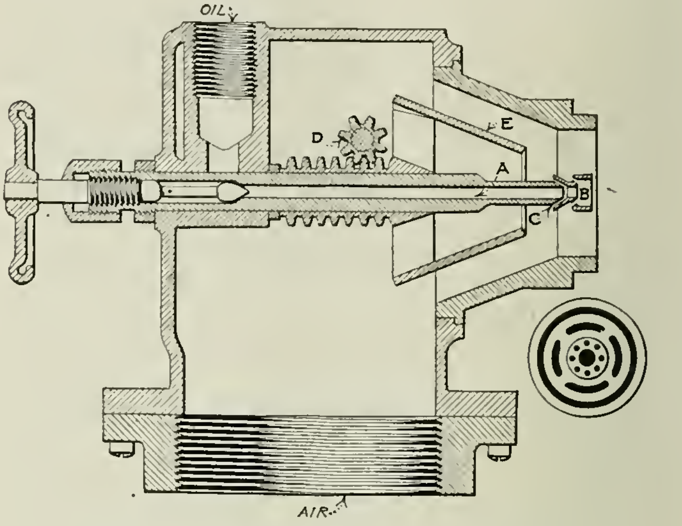
The only way to remove the nut is to release the ball from its lock position, which is done by inserting a pin through the keyhole shown in Fig. 2. Should the keyhole become filled with dirt it is easily cleaned by inserting a small pin or wire.

Lindsay Low-Pressure Oil Burner

The Lindsay oil burner has recently been placed on the market, and although it was primarily designed for use in assay and metallurgical plants it will doubtless be found suitable for use by engineers for heating small furnaces, etc. It has a central channel *A* through which the oil flows; the oil is discharged through an enlarged orifice *B* in a thin circular film. It is caught by a rotating blast of air and thrown from the nozzle as a fine swirling mist. The burner is manufactured by the Mine and Smelter Supply Co., New York City.



SECTION THROUGH LINDSAY LOW-PRESSURE OIL BURNER

Part of the air supply passes through the tip of the innermost orifice at *C*, thus preventing the clogging of the oil line. The burner will work successfully on any oil from a heavy one of 18 deg. Baumé to the lightest gas oil. As there are no delicate parts to clog, it is not necessary to take the burner apart frequently for cleaning, although all parts are accessible if for any reason it is desirable to open the burner. The oil consumption is low, running from 1 to 1½ gal. per burner per hour for the smaller sizes, up to 2 gal. and up for the larger ones.

The air pressure required for the Lindsay low-pressure burner is from 6 to 8 oz. On account of the burner construction this pressure gives perfect atomization, while the oil is fed to the burner by gravity. The air supply is controlled by merely turning a regulating adjustment situated on the side of the burner and which does not get hot. This can be done instantly and while the burner is in use.

As the adjustment is turned that reduces the quantity of air, a movable cone *E* decreases the area of the air vent, so that the pressure remains constant, though the volume is less. This prevents loss of efficiency, which would occur if a less quantity of air were permitted to go through the same sized orifice. This movable cone is regulated from the adjustment on the side of the burner through a rack and pinion *D*, and is held in position by a pawl and spring so that the adjustment will not change.

Where Does the Heat Go?

Of the total amount of heat energy represented by the coal fired in a boiler furnace, only from 6 to 15 per cent. is obtained in the form of useful work at the belt wheel of the engine. This article shows where and how the heat is lost.

ONE pound of good coal has a heating value of 13,500 B.t.u.; but when that coal is burned under a boiler and the steam produced by it is used in an engine, the work obtained at the belt is only a small fraction of the energy contained in the fuel. The reason is that the greater part of the heat is lost in various ways.

A part of each pound of coal drops through the grates and is carted away with the ashes. As this coal is not burned, its heating value is not given up, and heat is thus thrown away. The loss in any particular case will depend on the kind and grade of coal, the form of grate and the skill of the fireman. As an average, the loss may be taken as 1 per cent., or 135 B.t.u.

The furnace is inclosed in brick, and the steam drum is protected by a nonconducting covering; but even these precautions cannot wholly prevent heat from being radiated from the boiler. The amount thus lost may be assumed to be 5 per cent., or 675 B.t.u.

The two losses just mentioned, however, are small when compared with the loss due to the escape of the hot gases at the top of the chimney. About 2970 B.t.u., or 22 per cent. of the heating value of the coal, passes away through the chimney.

Of the 2970 B.t.u. thus lost, much is used in heating the air supplied to burn the coal. The air entering the ashpit has a temperature of, say, 60 deg. F., but the gases escaping at the top of the chimney have a temperature of 500 or 600 deg. F. This large increase of temperature requires heat, which is taken from that developed by combustion of the coal.

The chimney gases also contain steam, formed by the combustion of the hydrogen in the coal as well as by the vaporizing of the moisture in the coal and in the air supply. A part of the 2970 B.t.u. is accounted for by the escape of this steam.

Further than this, there may be unburnt carbon and hydrogen in the chimney gases. If all the carbon is not burned to carbon dioxide (CO_2) and all the hydrogen is not burned to steam, the escape of these unburnt combustibles represents a loss of heat. The loss due to combustibles in the chimney gases accounts for the remainder of the 2970 B.t.u.

The three items of loss thus far considered total 28 per cent., which represents the boiler loss. The difference between this and 100 per cent. is 72 per cent., which is the boiler efficiency; that is, the boiler puts into the steam 72 per cent. of the heat it receives from the coal. At this efficiency, therefore, the boiler utilizes 13,500 × 0.72 — 9720 B.t.u. per pound of coal burned.

A part of the heat in the steam—say 10 per cent., or about 1000 B.t.u.—is needed to run the feed pump and other auxiliaries; but when these are run noncondensing, it is possible to reclaim about 780 B.t.u. by passing the exhaust steam through a feed-water heater. In this way the amount of heat put into the steam for each pound of coal burned is 10,500 B.t.u. When the steam is conveyed through the main pipe to the engine and pumps, there is a further loss due to radiation and leakage, amounting to about 210 B.t.u.

The pipes and cylinders of the auxiliary apparatus are often left bare or are not well covered, and of the 1000 B.t.u. delivered to them, about 3 per cent., or 30 B.t.u., is lost by radiation. As 780 B.t.u. is reclaimed in the heater, it follows that 1000 — (780 + 30) = 190 B.t.u. is lost in the exhaust from the heater.

Of the 10,500 B.t.u. in the steam, 1000 + 210 = 1210 B.t.u. is accounted for by the radiation losses and the demands of the auxiliaries. The remainder, or 10,500 — 1210 = 9290 B.t.u., is delivered to the engine. Leakage and radiation from the steam chest, cylinder, etc., will cause a loss of about 3 per cent., or 280 B.t.u., so that the heat left to be converted into work is 9290 — 280 = 9010 B.t.u.

A good modern condensing engine will probably produce a horsepower on 2 lb. of coal per hour, or half a horsepower on 1 lb. of coal per hour. A horsepower is 33,000 ft.-lb. per min., or 1,980,000 ft.-lb. per hour, and as 778 ft.-lb. is equivalent to 1 B.t.u., a horsepower requires 1,980,000 ÷ 778 = 2545 B.t.u. per hour. As the engine is assumed to produce half a horsepower, it will use 2545 ÷ 2 = 1272.5, or, say, 1273 B.t.u. per hour. If only 1273 B.t.u. is utilized in producing power, the remainder, 9010 — 1273 = 7737 B.t.u., represents the heat discharged into the condenser and carried away by the circulating water and the condensate.

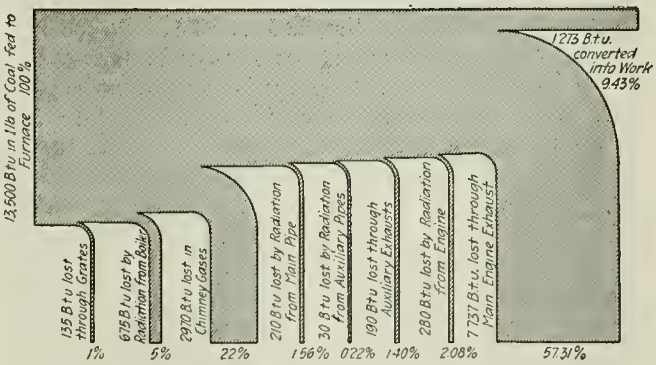


DIAGRAM SHOWING HEAT LOSSES

Not all of the 1273 B.t.u. converted into work is available at the belt wheel, for friction will waste about 8 per cent., even in a good engine. If the engine is assumed to have the high mechanical efficiency of 92 per cent., therefore, the heat equivalent of the work available at the belt will be 1273 × 0.92 = 1171 B.t.u. Thus, from 13,500 B.t.u. put into the furnace in a pound of coal, only 1171 B.t.u. is converted into useful work. This is equivalent to 1171 ÷ 13,500 = 0.0867, or 8⅔ per cent., of the heat in the coal.

The accompanying diagram shows graphically the various heat losses, expressed as percentages of the heating value of the coal. It is evident that the largest losses are those due to the hot chimney gases and the exhaust steam from the engine, and wherever the losses are greatest, opportunity for saving is greatest.

Federal Inspection of Power Plants

Power Plants Must Be Efficient As Well As Safe
The Needlessly Wasteful the Last To Get Fuel

IT HAS been definitely determined by the United States Fuel Administration to institute a system of classification of power plants, based upon the care and efficiency with which they are operated, and the idea has received the approval of fuel administrators in New England, Connecticut, New York and Pennsylvania. The details have been worked out by David Moffat Myers, Advisory Engineer of the United States Fuel Administration.

It is estimated that from 25,000,000 to 50,000,000 tons of coal per year can be saved in power plants, simply by the more careful and intelligent use of existing apparatus and the elimination of easily preventable waste. To effect this purpose an Administrative Engineer will be appointed in each industrial state, to be attached to the office of the State Fuel Administrator. W. R. C. Corson, of the Hartford Steam Boiler Inspection and Insurance Co., is to be the engineer for Connecticut; E. N. Trump, vice president of the Solvay Process Co., for New York; Thomas R. Brown, of the Westinghouse Air Brake Co., of the Pittsburgh district; and Walton Clark, vice president of the U. G. I., of the Philadelphia district of Pennsylvania. Other states will be organized as fast as possible. A questionnaire will be sent by these engineers to the owner or operator of each fuel-operated power plant in the state, asking him to furnish the administrator within a stated number of days such information as the type and number of boilers; kind of service or product; kind of draft and method of firing; amount and kind of coal burned during the preceding 12 months; proportion used for power, heating and process work; amount of purchased power; whether records of coal consumed, water evaporated and flue-gas analysis are kept; type and size of steam-using units; what provisions are made for weighing coal and water, and what records are kept; what provision is made for heating feed water; if means are provided for measuring the draft over the fire and for determining excess air by gas analysis; if dampers are provided for equalizing the draft in the furnaces; if there is a convenient means for regulating the draft by the main or uptake dampers; if there is an automatic damper regulator in working order; what provision is made for keeping soot and ashes from boiler-heating surfaces; whether the grates are warped, broken or otherwise defective; whether there are leaks in boiler settings, openings between boiler and setting, badly warped fire-doors, etc.; if heat-radiating surfaces are covered; if the exhaust steam from noncondensing engines is used and to what extent; if live steam at low pressure is used in the plant and for what purposes; if a competent man is detailed to supervise the work of fuel conservation in the boiler and engine rooms and the transmission and use of power in the factory.

Arrangements have been made whereby inspectors of the steam-boiler insurance companies, state factory inspectors, engineering students from technical colleges, volunteers and others will visit these plants and verify the answers given in the questionnaire. Each plant will be given a rating, based upon the data so obtained. The ratings will be divided into five classes, and in case of a fuel shortage the plant that has been found to be needlessly wasteful will be one of the last to be allowed to draw upon the available supply.

It is recognized that plants must be dealt with as they are found. No extensive and expensive installations of more efficient apparatus will be expected, but there are many economies that can be brought about by stopping leaks in boiler settings, repairing baffles, covering heat-radiating surfaces, trapping outlets, returning drips and making an intelligent use of the exhaust. A plant will be judged, not on its inherent efficiency as a plant, but by the use which it makes of its own conditions and opportunities. The whole attitude of the administration will be one of suggestive helpfulness rather than of coercion. The inspectors who visit the plants to verify the questionnaires will in many cases be able to give sound advice, and the State Administrator will be furnished with a list of approved professional consulting engineers to whom power-plant owners may turn for more extensive consultation.

The Fuel Administration is also preparing a series of official bulletins on Steam and Fuel Economics. These will include boiler and furnace testing, flue-gas analysis, saving steam in heating systems, boiler-room accounting systems, saving steam and fuel in industrial plants, burning fine sizes of anthracite, boiler-water treatment, oil burning, stoker operation.

Burning Natural Gas Under Boilers

By Charles Jablow

On account of the present interest in fuel conservation it may be interesting to note the saving effected in one plant from a study of the operating conditions.

The plant, containing 770 rated boiler horsepower, was using as fuel natural gas, at a pressure of over fifteen pounds. Three of the boilers had four burners each. It was found by several evaporation tests that by reducing the pressure to about two or three pounds the equivalent evaporation was changed from 0.471 to 0.494 lb. per cu.ft. of gas, the highest heating value of which was 619 B.t.u. per cu.ft. But with this pressure reduction there was a reduction in the boiler horsepower from 212 to 148, partly because the gas main leading to the plant is only 3 in. in diameter and the pressure change was made at a gas regulator about 1000 ft. distant, so that with the lower pressure the capacity of the line was reduced too much. I recommended that the regulator be moved to the plant and that the 3-in. line be subjected to the high pressure of the main. An additional burner was put under each boiler at the same time, and our expectations relative to the performance of the boilers were fulfilled and the rating of the boilers was easily developed.

The fuel bill for the last few years has been about $10,000 annually, and the saving by these changes amounts to about $450 per year.

Editorials

Government Insistence Upon Power-Plant Efficiency

EVER since its foundation *Power* has insisted upon Governmental regulation of power plants. It holds that the owner of a factory or a department store has no right to invite the public into a building in the cellar of which are boilers upon the safety of which no competent authority has passed, operated by laborers selected for their willingness to work for meager pay rather than for their knowledge of the forces with which they are dealing. Regulation and inspection exercised by foreign governments have reduced casualties until the number of those in the United States is by comparison lamentably high in proportion to the number of boilers in use.

It appears to be axiomatic that it is not only the right but the duty of the Government to look after the safety of the citizen. Several years ago we ventured a suggestion that the time might come when the Government would insist upon efficiency as well as safety in the operation of power plants. If a boiler explosion is a communal disaster, adding, through its destruction of buildings, plant and material, its interruption in production and reduction of output, in increased rent and insurance and prices of product, and in care of the injured and dependent, to the burdens of the community, how much more of a communal disaster is a sustained waste, going on year after year, using up the resources of the country and paid in the final analysis by the ultimate consumer. The idea has found expression by others and would have found justification and adoption in the course of ordinary events.

But the war has produced a condition of fluxibility in which the fixed patterns and formulas of an old conservatism are torn loose and jostled about with a chance of setting down upon lines which are sound and right and capable of producing results. And so, quite naturally, when the scarcity of fuel becomes pressing the people—that is the Government—say: "Why should this man be allowed, through simple carelessness, to burn twice as much coal as he needs, making his product (if its selling price is based on its cost as it should be) cost more to its users, using up man-power and railway facilities to get coal to waste while others suffer for the want of it?"

Over forty per cent. of the coal mined is used in industrial plants. A saving of even ten per cent. in this field would go a long way toward making up the shortage. The Fuel Administration has resolved to put this saving into effect. An engineer will be accredited to the Fuel Administrator of each of the industrial states, and under his direction a questionnaire will be sent to the owner or operator of every fuel-operated power plant in the state. The replies to this questionnaire will enable the state engineer to determine whether the plant is being operated with care and intelligence or needlessly wastefully. Inspectors will visit the plants, verify the answers returned and offer helpful suggestions. No insistence will be put upon the installing of more efficient apparatus, but an effort will be made to get the best results out of present equipment with such simple improvements as can be made under existing conditions and improved methods of operation. In the light of the information thus obtained, the plants will be classified, and those which use their fuel with the least care and intelligence will be the last to get any when the shortage comes. The attitude of the Administration will, however, be suggestive and helpful rather than coercive. The inspectors will not be called upon to advise as to possible improvements in apparatus and methods. The state administrators will be prepared to recommend reliable professional engineers for those who care for more extensive advice.

One of the beneficial results of this action will be to direct the attention of the office to the power plant. In the interim allowed between the receipt and the filing of the questionnaire, the owner or his representative will be interested to get the plant into as creditable a condition as possible so as to get as far as possible from that lower stratum which will be the first to be deprived of coal. This will be the opportunity of the engineer to get much-needed apparatus and to have repairs and overhauling done, his recommendations for which have not met with a favorable response in the past.

The movement ought to result in the improvement of a multiplicity of plants and the saving of many tons of coal, and should receive the hearty approval and coöperation of plant owners and operators and of fuel administrators everywhere.

Work or Fight

THE latest amendment to the selective draft law, recently announced by Provost Marshal General Crowder, whereby, after July 1, every man of draft age must either go to work in employment essential to winning the war or join the fighting forces in France, is the most encouraging news that has come from the Provost Marshal's office for some time and should be received by every American with red blood in his veins as a wholesome change in our military policy. According to the order gamblers, race-track and bucket-shop attendants, fortune tellers and idlers head the list, followed by waiters, bartenders, theater ushers and attendants, passenger-elevator operators, attendants at clubs and hotels, domestics, clerks in stores, baseball players, jockeys, professional golfers, and other professional sportsmen. Looking this list over, it would appear that the Provost Marshal has an excellent insight into non-essential industries as far as men in their prime are concerned, since many of those listed, especially the first five, the nation can well do without not only in times of war, but in peace also, with profit to itself. The other occupations might be considered healthy men's jobs when the nation is at peace, but they certainly can all be filled by women or men too old to enter the industries or the fighting ranks or dispensed with entirely when the nation is facing a shortage in its man power like the present.

We have long passed the time when we can afford to allow able-bodied men to loaf away their time in poolrooms, on park benches, in dance halls and cabaret shows, while millions of others are working overtime in our industries to supply the sinews of war for other millions we are sending to the battle front to suffer all the privations of modern warfare and die if need be to make the world safe for democracy.

There has been considerable discussion as to what are nonessential industries and who is able to distinguish between the nonessential and essential. However, General Crowder seems to have attacked the problem by a process of elimination and has excluded the least essential at first. Although his first step is a modest one, there is no doubt that if the war continues for a considerable period longer this ruling will be extended to other industries until every able-bodied American citizen will be either in the military forces of the country or engaged in industries essential to the war machine. This latest ruling should give assurance to many that whatever may be termed semiessential industries of the country will not be robbed of their employees until at least every able-bodied loafer has been put to work or fighting, and that the Provost Marshal intends to meet the emergency with as little hardship to the country's industries as possible.

Boiler Settings

WITH the advent of high combustion rates on stokers and the quest for economical production of steam, to say nothing about smoke abatement, the matter of boiler furnace design became one of the important factors in power-plant practice. The wider use of the Middle-Western coals and lignites, both high in volatile, together with the desire in many quarters to burn these fuels at high combustion rates, gives added significance to the boiler setting or combustion volume.

In 1913, when the water-tube boilers in the Two Hundred and First Street station of the United Electric Light and Power Company, New York City, were set ten feet from bottom of front header to the floor line, there was general explanation. Today, engineers will do much to overcome any obstacle that stands in the way of setting this type of boiler less than twelve feet above the floor, even for Eastern low-volatile coal and a combustion rate of 250 per cent. builder's rating of the boiler. One finds boilers set thirteen and even fourteen feet here in the East, while boilers of the Stirling and Connelly types are being set with the center of the mud drum anywhere from eight feet for high-volatile coal to over eleven feet for lignite, when burned on underfeed stokers. Not only do engineers recognize the value of large combustion volume, but one finds all builders of stokers urging a minimum height for settings, varying with the boiler and coal and combustion rate. In those plants which change over from hand-firing to stoker-firing, nearly all builders of stokers will refuse the job if the prospective purchaser insists on too small combustion volume.

The articles now appearing in *Power* on the subject of boiler settings are valuable not only because they show what is current and excellent practice for high-volatile coal particularly, but because the numerous drawings carry all important dimensions, and in addition numerous performance data will be presented.

Concrete Boilers Next

CONCRETE construction has entered many fields of commercial enterprise, and although at one time opinions might have been held that it was suitable only for sidewalks and not any too good at that, the art of concrete construction has developed into broad channels, so much so that entire buildings are made of it. Its latest application is that of concrete ships. Now, according to the *San Francisco Chronicle*, cement may be used in the construction of boilers in the near future, as it is understood that an experiment will be made at the Union Iron Works. The report says that considerable figuring has been done and numerous sketches have been made, and that a boiler will be constructed shortly. It is stated that it is expected that with the exception of the boiler shell there will be but little change, and instead of one thick boiler sheet the new construction of shell is to consist of two thin sheets of steel, probably one-quarter inch in thickness, and these will be fastened together, leaving between them two or three inches of space, which will be filled with a high-grade cement.

In these days of progress and invention one is not safe in asserting that this or that proposed idea will not work out satisfactorily. It is only a few years ago that the practicability of the steam turbine was earnestly disputed. It is only a few months ago that the practicability of building a concrete ship was seriously doubted, and although it is early to state whether the concrete ship will be a success as compared with steel-ship construction, the odds are in its favor. So to condemn the concrete boiler before the idea has been tested out would be, perhaps, premature, although one is inclined to wonder what will occur to the concrete when the boiler expands from a cold state to the temperature it will have when under working pressure.

There are 2,078,222 now in the Army; a million men ready to embark; ninety thousand sailed in the first ten days of May. All thoroughly equipped. America can raise an army of five million this year without going outside of Class One.—*Representative Caldwell, of the Military Affairs Committee, to the House.*

The American shipyards are averaging one steel ship a day. May output more than 200,000 tons. Two ships just launched were completed from keel to aërial in fifty-five days, and one in fifty-seven days. In the next eighteen months six hundred ships will be put in commission on the West Coast alone. Ten steel ships were finished and eighteen others launched in one week.

Yes, indeed, the Yanks are coming.

The latest advices from Boston are to the effect that Garabed Giragossian is suffering from an attack of constipation of energy.

Correspondence

North Dakota Lignite for Boilers

Your editorial and Henry Kreisinger's article on the combustion of North Dakota lignites, in *Power*, Apr. 30, are interesting and instructive. To those not familiar with the fuel it may appear that our lignite is not suitable for steam coal except with a specially designed furnace and grate. All the power plants in the western part of this state are using lignite successfully in ordinary furnaces provided with suitable grates, and we are obtaining efficiencies equal to those had when burning bituminous coal in the eastern part of the state, where, I have noticed, it required 78,000 B.t.u. in the coal for generating one kilowatt-hour. Under the same conditions with lignite we are generating a kilowatt-hour on 61,000 B.t.u. These figures are based on units that consume 40 lb. of water per kilowatt-hour delivered to the circuits and Eastern coal containing 13,000 B.t.u. and lignite 7000 B.t.u.

The same conditions prevail in flour making when comparing heat units required per barrel in Minneapolis with mills operated by lignite in this part of our state. It will therefore appear that here is a reason for suggesting a furnace for burning bituminous coal more efficiently.

The reason that our lignite is not used more extensively in the eastern part of North Dakota and neighboring states is the cost of transportation. It seems that the railroads have not favored it, as the rates on lignite from the mines to the eastern border of the state, a distance of about 210 miles, is $1.25 the ton; and in the next zone east of the border line the rate is $2.15 the ton; the freight on lignite to St. Paul and Minneapolis, a distance of about 500 miles, was about equal to the cost of Pennsylvania slack coal laid down there before the war.

On the border line the prices of Pennsylvania slack and our lignite were about equal and nobody would give the latter any consideration. No doubt the railroads took the advantage of shipping all our grain and stock to Minneapolis, St. Paul and Duluth and had cars returned this way loaded with coal from the harbor at Duluth. The rates on coal from Buffalo to Duluth via the lakes is very low. There was no market for our lignite, but since the shortage of the Eastern coal and congestion in transportation had been severely felt, people living in these zones have begun to look in our direction for their next winter's fuel supply.

The railroads now have the lignite rates under consideration, and the real value of our low-grade fuel will soon come to its right.

In this part of our state the poor man's fuel for domestic use is lignite. Those who can afford to burn anthracite do so regardless of its cost. Some would abuse lignite to a great extent even if we have beds 8 to 18 ft. thick, covering over 30,000 square miles. Some of this is surface coal that contains about 6000 B.t.u. per pound.

The largest mine in the state is in Burleigh County, the coal from which runs on an average of 7000 B.t.u. The best coal known to the writer is in Mercer County and runs on an average of 7500 B.t.u. A recent sample showed a commercial heating value of 8058 B.t.u., 30.6 per cent. moisture, 5.3 per cent. ash, 31.9 per cent. volatile matters, 32.2 per cent. fixed carbon and no sulphur. The same coal dry showed 11,611 B.t.u., 7.7 per cent. ash, 45.9 per cent. volatile matter and 46.4 per cent. fixed carbon.

Under fair conditions one pound of this will evaporate 6.25 lb. of water from and at 212 deg. F. This is equal to evaporating 10.86 lb. of water from one pound of coal containing 14,000 B.t.u., but to obtain such efficiency from lignite the volatiles or gases must be ignited in the furnace during their course of travel over the bridge-wall and through the combustion chamber. Forced draft and a near balanced draft is required, but the force of the draft under the grate is the most essential point to be adjusted.

Mr. Kreisinger suggests a large air space for grates of the inclined type. The same idea appealed to me, but I had to reverse myself, and I am now constantly cutting down the air space; I am now burning lignite on a flat sawdust grate having only 11 per cent. air space, and by doing so can maintain a higher air pressure under the grate. Lignite does not require a large volume of air for its combustion—about 75 cu.ft. of air per pound of lignite is sufficient. The clinkers accumulating on the grate from a lignite containing little sulphur are porous, and air passes through them quite freely with high air pressure under the grate. By keeping a few inches of water in the ashpit, there is little fire below the grates. The first set of sawdust grates, installed 12 years ago, is still in service.

It is not advisable to fire a boiler above its rated capacity when efficiency is considered, and with a ratio of 1 sq.ft. of grate surface to 50 sq.ft. of heating surface 40 lb. of lignite can be burned economically per square foot of grate surface per hour. With such conditions a flue-gas temperature of about 450 deg. F. with an average of 12 per cent. CO_2 can be maintained. Boilers equipped with economizers may be forced to a great extent as the excess heat in flue gases would not all be wasted.

When burning lignite the combustion chamber fills up rapidly with small particles or sparks from the fuel on the grate, and it has been discovered that the highest efficiency is not obtained until there has accumulated a 3- to 4-in. coating of those slow-burning particles all through the combustion chamber and over the bridge-wall; therefore, when one receives a carload of lignite for a test and is not familiar with the characteristic of the fuel one generally gets disappointing impressions.

The cost of lignite f.o.b. the mines set by our Fuel Administrator is $2.50 per ton for screened lump, $2.25 for screened 6-in. coal, $2 for mine-run and $1.25 for screenings that have passed through a 2-in. screen. The screenings give the most suitable size of coal for boiler use, although they often contain a large amount of dirt. In mining our coal an undercutting machine is used, the cuttings from this machine go into the screenings and if the operator of the machine is not careful, he is liable to cut into the dirt or clay below the coal bed; this mixed with the coal makes it an unsatisfactory fuel. On the other hand, 6-in. coal is too large a lump for a steam coal; much of our lignite breaks up in slabs similar to sandstone, and such slabs lying flat on the burning coal smother the fire below them. Those familiar with burning lignite in stoves and heating furnaces will place those slabs up edgeways and pack the firepot full of it and get results. As this cannot be done under boilers, the coal must be broken or crushed to 3 in. and less to get efficiency.

In your editorial you speak of pulverizing lignite for use in the furnace. That process has been under much discussion through the columns of *Power*, and from what I learned from reading those columns there is no gain in burning a high-grade powdered coal when considering the cost of drying, pulverizing, maintaining the furnace walls and the excess air admitted to the fuel in the process of burning it. The cost to pulverize a pound of low-grade coal is practically the same as a pound of high-grade coal, and the moisture must also be disposed of before the lignite is pulverized.

Lignite will absorb moisture from the atmosphere after it has been dried; therefore, I doubt the possibility of burning it in that form. You also say that lignite in a natural state cannot be transported even short distances from the mines for the reason that the moisture evaporates, causing the substance to break up in small chunks and flakes and if subjected to much jarring it disintegrates into powder, all of which makes the fuel inconvenient to handle.

Lignite will slack to some extent when exposed to heat, but nobody here worries about that. We are now advised by our fuel administrator and governor to fill up our coal bins so the mines can be kept in full operation during the summer. We will then be able to send South Dakota and Minnesota lignite next winter.

Bismarck, N. D. C. P. Larsen.

Different Rate of Scale Formation

In the issue of Apr. 16, page 559, Mr. Lewis suggests that scale formation is greatest on the side of the boiler nearest the soot-blowing openings because there is less soot on the tubes on that side, etc.

We have trouble here with scale forming in nine tubes out of eighteen, and these nine tubes are not always those nearest the soot-blowing openings, while in the letter by Thomas Pascoe in the issue of Apr. 9, page 521, he states that it is always the tubes next to the soot-blowing openings that scale most. We use oil fuel, have three burners in each furnace, have the dampers exactly alike and run with the stop valves for the feed water full open on all drums, but there are always nine tubes with scale (of course that is the number for each drum), and always the same ones. It is not likely that burners in certain locations always give out much more or less heat than the others; besides, changing the position of burners is a common occurrence.

Anyox, B. C., Canada. J. B. Tait.

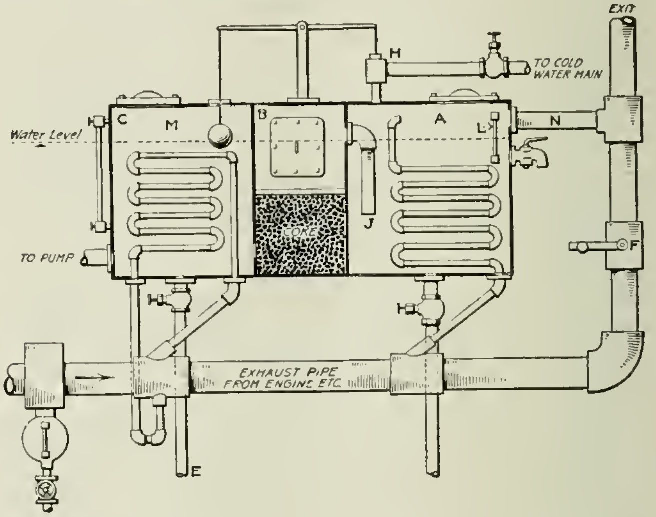
Plugged Holes in Piston

I recently had an experience with an engine that may be of interest. I first noticed a rather dull thumping in the cylinder as the piston came to the head end of the stroke. I realized that something was wrong, and at the first chance I removed the cylinder head and to my surprise found a hole in the piston about three-fourths of an inch in diameter with a crack extending on each side. I reamed out the hole and screwed in a 1¼-in. flush pipe plug and drilled a ⅛-in. hole at each end of the crack to prevent its extending further, and have had no trouble since. C. Richard Ward.

Willsboro, N. Y.

Feed-Water Heater and Filter

The illustration shows a heater and filter of my own design, which can be built of quarter-inch boiler plate or cast-iron plates and may be either round or square, although I prefer the latter. A live-steam connection, with a reliable pressure-reducing valve attached, supplies steam for heating the water when there is no exhaust steam. Traps discharging clean condensate from live steam can be connected into part *C*, but if the condensate contains any oil it should go to compartment *A*. There are manholes in each compartment for cleaning, and drains to the sewer are provided, also an overflow *M* to the sewer, in case the makeup cold-water supply control should get out of order. The back-pressure valve *F* is set at a pressure just enough to cause steam to circulate up through the coils into the tank. In the center compartment there is a deep bed of coke, on top of which are several thicknesses of burlap bags and over these about ten inches of excelsior.



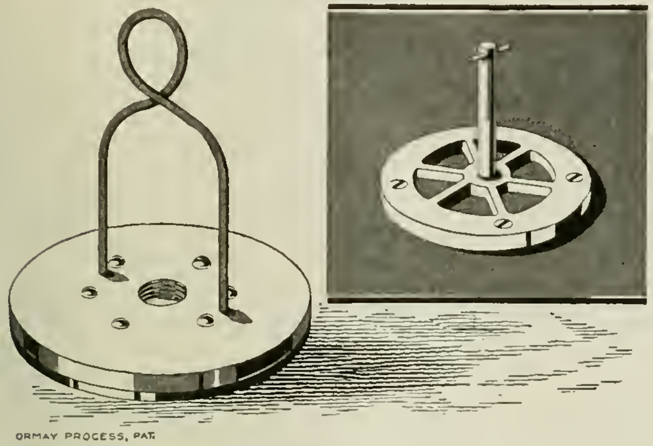
HOME-MADE FEED-WATER HEATER AND FILTER

The water supply enters compartment *A*, passes up pipe *J*, down through compartment *B* and into *C* at the bottom, thence to the pump. Most of the sediment will settle in *A* and the oil will float to the top, but if any does escape it will be collected in the filter. Part *A* will require cleaning quite often, but *B* only once in about three months and *C* once in six months. Pipe *N* acts as a relief to guard against an accumulation of pressure should the valve *F* be set too heavy.

Portsmouth, Ont., Canada. James E. Noble.

An Easily Made Draining Valve

The illustration shows a simple valve for draining tubs and tanks. The disk is cast iron with a ¼-in. cloth insertion rubber packing riveted to it, and the seat is similar to that of a pump, as shown, fastened to the bottom inside of the tank with screws countersunk flush with the surface of the seat. I have made a number of 4-in. valves of this type, and they were entirely satisfactory. The sheets of soft-rubber packing make a tight joint that will give, and close around any small object that may get under the disk.



OUTLET VALVE FOR BOTTOM OF TANK

New Bedford, Mass. H. K. Wilson.

Cleaning Condenser Tubes with Muriatic Acid

Regarding cleaning condenser tubes with muriatic acid, as noted by Mr. McKeehan on page 504 in the issue of Apr. 9, we have found here, in Grand Rapids, that the method is effective, economical and not injurious to the tubes.

The city is supplied with a lime-softened water averaging about six grains of scale-forming matter per cubic centimeter and, like all lime-softened waters under certain conditions of heat and pressure, tends to deposit a small amount of carbonate of lime, which in time becomes more or less serious on the surface of condenser tubes. At the city pumping station two of the pumps are equipped with condensers containing approximately 1400 one-inch tubes about seven feet long. In a year's time these tubes become so coated over as to drop the vacuum from about 28 to 24 in., a matter serious enough to require attention.

For the last two years the method of cleaning these tubes has been to disconnect the condensers and swing them clear of the suction connections, apply blind flanges to the inlet and outlet sides and fill them up with water to which has been added a first dose of 20 to 25 gal. of muriatic acid. Steam lines are connected in and this charge is boiled two hours or so till the acid has been used up, then more water and acid added, say five to seven gallons, till the tubes are boiled clean. Usually we have found about 55 gal. of acid sufficient, and boiling greatly hastens the work; a day is usually ample time to do a good job. This method has worked equally well in cleaning the oil-cooling tubes of our turbo-generators.

For the last three years an acid cleaning method has been used in the condensers at Columbus, Ohio, where the water supply is similar to that of Grand Rapids, and the type of the condensers does not readily admit of their being removed. In this case the acid is sprayed on with a force pump, a small fan being set up behind the men manipulating the spray to carry the fumes of the acid through to the other side and away. I understand that this method also works satisfactorily.

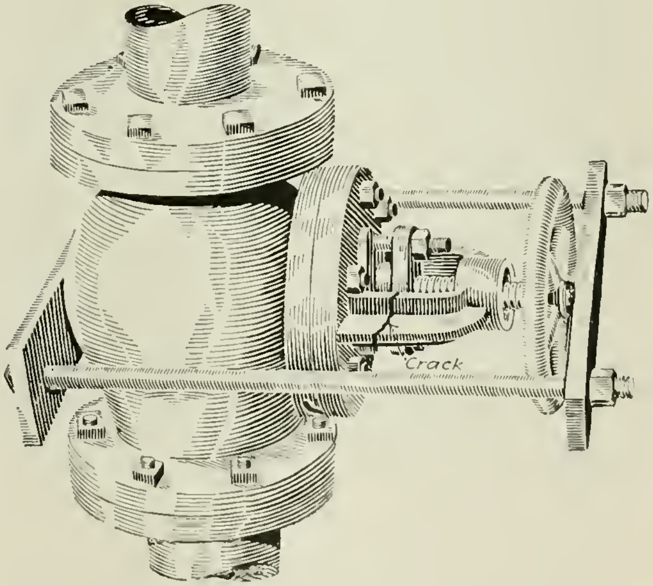
Grand Rapids, Mich. Walter A. Sperry.

Some Emergency Valve Repairs

In the plant where I am operating I recently had a little trouble with a 2½-in. throttle valve on a pump. The valve had broken at the yoke, due to water-hammer. As I did not care to use this pump as much as I did another one on the same line, I obtained two 2 x 4-in. pieces of iron and drilled holes through them, and placing one piece below the valve body and the other against the nut on the valve-wheel stem, the two were drawn together, and the cracked yoke back to place with the long bolts and nuts, as shown in the illustration.

A few days ago one of the pumps worked badly, becoming air-bound; when stopped, there was a continuous stream of water coming from the pump, which could not be stopped unless the glands were screwed up very tight. An examination showed that a 5-in. check valve was unseated, the bottom guide having been broken off and the top guide badly worn on one side. Not having another valve of that size in stock, I proceeded to repair the broken one as follows:

I took the top half of the valve to which the guide for the bottom is fastened, drilled a ½-in. hole through it, and then resurrected an old valve stem ½ in. diameter and cut it to the proper length and riveted it in the place of the one that had been broken off. The worn upper guide was cut off with a hacksaw and treated in the same manner as the lower guide. The valve was back in place in less than one-half hour, and it has worked as well as a new one ever since.



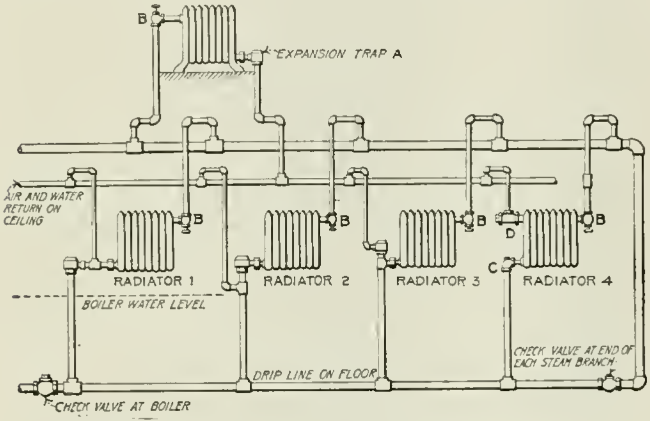
CRACKED YOKE DRAWN TOGETHER

Fort Apache, Ariz. Robert E. Leech.

Radiator Connections

One type of steam-heating system uses a small expansion trap on the outlet of each radiator, a return trap to put the water back into the boiler, and one air valve to let air out of the whole return system. The small traps on the radiators let air and water pass, but close against steam. The common air and water return must be above the water level of the boiler.

In one instance it was necessary to connect some wall-type radiators below this common return line, but still above the boiler-water level. They were first connected as radiator 1 shown in the illustration (the others being marked 2, 3 and 4). The air was expected to go to the air and water return and the water to go down through the radiator trap into the drain from the steam mains; but steam, blowing through these radiators and backing up to the radiators on the upper floors, shut the outlet traps and closed the air valve at the boiler, so the air could not clear from the system and the water would not return from the radiators—the system became steam- and air-bound.



RADIATOR CONNECTIONS TRIED OR SUGGESTED

The connections were then changed as shown in the next case (radiator 2), but on the first cold day the steam pressure forced the water out of the drip line, along the floor, and caused water-hammer. Connection 3 was considered as a remedy, but as the traps do not close against water unless it is near the boiling point, this plan was discarded and connection 4 adopted. As steam is lighter than air, it passes across the top of the radiator and closes the air valve while the lower half of the radiator is cold, but by letting the air valve blow a little steam, the radiator gradually clears of air and the small blow of steam does not interfere with the rest of the system. Discussion and any suggestions for improvement will be welcome.

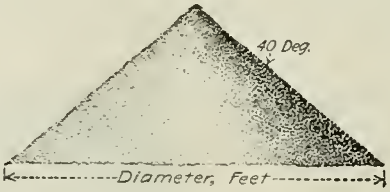
Washington, D. C. **MORRIS ELLISON.**

Weight of Ashes in Conical Pile

The angle of repose for ashes in a conical pile, that is, the angle made by the sloping side of the cone with the horizontal, as shown in the accompanying illustration, averages 40 deg. The average weight of ashes per cubic foot is 40 lb. Based on these two figures, it follows that a formula can be developed suitable for determining the weight of any conical pile of ashes. All that is necessary is to measure the diameter of the base. The formula is as follows:

$W = 4.4\,d^3$ = weight of conical pile of ashes in pounds. where d is the diameter of base pile in feet.

To illustrate: The diameter of a pile of ashes is 8 ft. Then $8^3 = (8 \times 8 \times 8) \times 4.4 = 2253$ lb. of ashes



AVERAGE ANGLE OF CONICAL ASH PILE

in a conical pile having a diameter at the base of 8 ft. The accompanying table gives the weight of ashes in conical piles from 1 up to 100 ft. in diameter, and any intermediate diameter of ash piles not shown in the table can be easily computed. **W. F. SCHAPHORST.**

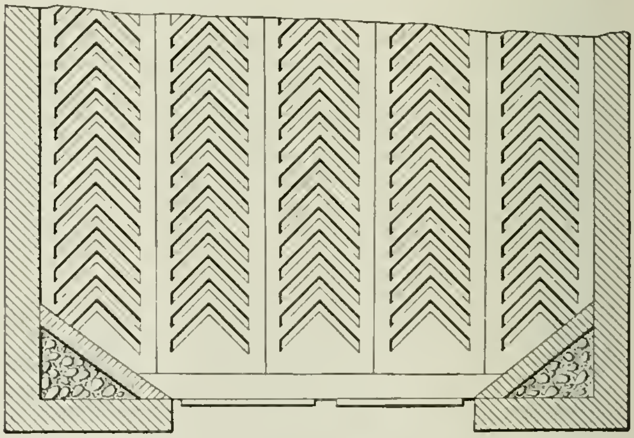
New York City.

WEIGHT OF ASHES IN CONICAL PILE

Diameter of Ash Pile, Feet	Weight of Ashes, Pounds	Diameter of Ash Pile, Feet	Weight of Ashes, Pounds
1	4.4	10	4,400
2	35	15	14,850
3	119	20	35,200
4	282	25	68,750
5	550	30	118,800
5.5	730	35	188,650
6	950	40	281,600
6.5	1,210	45	400,950
7	1,509	50	550,000
7.5	1,857	60	950,400
8	2,253	70	1,509,200
8.5	2,702	80	2,252,800
9	3,208	90	3,207,600
9.5	3,771	100	4,400,000

Boiler Firebox Improved

The illustration shows a top view of an improvement in the shape of the furnace under a return-tube boiler fitted with stationary grates. The bricks on the side wall and front were chipped out, and others were placed so as to cut off or fill in the sharp corners of the box, at the same time cutting off but little of the space. The object is to make it possible to clean the fire more quickly and to avoid the loss if these corners are neglected when cleaning or left uncovered when firing. The space behind the bricks was filled with pieces of brick and fireclay, and the top was sloped so that no coal or ashes can gather there.



BETTER RESULTS WITH CORNERS FILLED IN AS SHOWN

Flushing, N. Y. **WILLIAM F. WILLIAMSON.**

Inquiries of General Interest

Melting Point of Firebrick—What temperature will injure boiler-furnace firebrick? B. H.

When firebrick contains moisture or materials that have a higher coefficient of expansion than the binding material, the brick spawls and cracks with comparatively low temperatures. The melting point of ordinary commercial fireclay brick ranges from about 2700 deg. F. to 3200 deg. F., depending on the ingredients.

Pressure of Atmosphere from Height of Barometer—How may the pressure of the atmosphere be known in pounds per square inch from the height of the barometer? W. G.

At ordinary atmospheric temperatures the weight of a cubic inch of mercury may be taken as 0.491 lb. and the pressure of the atmosphere in pounds per square inch may be found by multiplying the height of the barometer in inches by 0.491.

Heat Required To Raise Temperature of Air—How many B.t.u. per hour would be required to heat 55 cu.ft. of air per min. from 62 to 300 deg. F.? J. C. E.

At 62 deg. F. there are 13.14 cu.ft. of air per pound. The specific heat of air is about 0.25, and to raise the temperature of a cubic foot from 62 deg. F. to 300 deg. F. would require $(300 - 62)\ 0.25 \div 13.14 = 4.52$ B.t.u., and for heating 55 cu.ft. per minute would require $4.52 \times 55 \times 60 = 14{,}916$ B.t.u. per hour.

Adding Heat to Constant Volume of Steam—If heat is added to steam in a closed vessel, would the temperature as well as the pressure rise? C. T. B.

The addition of heat would cause a rise of both temperature and pressure. The addition of sufficient heat would first convert any water present into dry saturated steam which would be of higher temperature and pressure than the original steam, and further addition of heat would still further raise its temperature and pressure to a superheated condition.

Iron Ball Pyrometer—How is the temperature of a boiler furnace obtained by heating a piece of cast iron in the furnace and afterward cooling it in water? G. R.

A piece of cast iron weighing 4 or 5 lb. and preferably of spherical or other compact form is allowed to remain in the furnace until it has attained the temperature of its surroundings. It is then suddenly plunged in a vessel containing a known weight and temperature of water and cooled while the water is being stirred rapidly until the piece of cast iron and the water attain the same temperature. The vessel may consist of a large bucket filled about three-fourths full of water and provided with a cover having a hole in it through which a perforated pipe extends to the bottom for the insertion of a thermometer. The hole in the cover may be large enough to use the pipe for stirring the water. If W = the weight of water, w = the weight of cast iron, t the original and T the final temperature of the water and S the specific heat of the cast iron, then the temperature of the piece of iron when placed in the water is found by the formula,

$$x = \frac{W(T - t)}{wS} + T$$

For example, if the weight of the piece of cast iron is 5 lb., the weight of the water 20 lb., the temperature of the water before the immersion 60 deg. F and after immersion 120 deg. F., and allowing the specific heat of cast iron at the furnace temperature to be 0.13, by substituting,

$$x = \frac{20(120 - 60)}{5 \times 0.13} + 120 = 1966\ deg.\ F.$$

Oil for Journal Bearings of Steam Dry Cans—In the textile-finishing business a machine is used that has steam-heated revolving cylinders called dry cans for which the steam used is conducted through the hollow journals on which the cans run. The bearings often attain a high temperature, and difficulty is experienced in keeping the bearings properly lubricated. What kind of oil would be suitable? O. M. W.

Most refiners of mineral oils are prepared to furnish lubricating oils suitable for use at ordinary temperatures of steam and, when informed of the pressure of steam supplied to the dry cans as an index of the temperature, would be enabled to select a product adapted to the conditions.

Testing Boiler-Feed Pump—How can a boiler-feed pump be tested to show that it is in fair working order? S. L. A.

Connect a steam-pressure gage to the steam-chest cover and a water-pressure gage with stop-cock on the delivery side of the pump. Then with a steam-chest pressure of about 50 lb. it should be possible to obtain a full bore of the delivery pipe when delivering against an equal water pressure. The pressure on the water-end gage is obtained by regulating the stop valve, and the discharge of water should be visible, and with equal steam and water pressure the water pressure gage should be reasonably steady. If the delivery of water stops while the pump is running, the fault will be due to leaky suction valves or piston slippage. Violent pulsations of the water-pressure gage usually will be an indication of leaky suction valves. When running slowly, if a piston travels suddenly to the end of the cylinder, the suction valve on that end will probably be the one that leaks most.

Determining Cylinder-Clearance Volume—How is the cylinder-clearance volume of an engine determined? H. N.

The cylinder-clearance volume is determined from the volume of water that can be contained by the clearance space when filled from the piston at the end of the stroke back to the valve seats. An opening needs to be provided at the top of each end of the cylinder for introducing the measuring water, or it may be introduced by the indicator connections provided suitable provision is made for the escape of air from the cylinder during the process of filling the cylinder with the measuring water. Place the engine on dead-center at the head end of the cylinder, and after removing the valves, cover each valve seat with a rubber gasket held down tight by a block of wood wedged or bolted in place. Remove the cylinder head and pack candlewicking around the piston to prevent excessive leakage of water past the piston.

Provide two vessels each filled with clean water and take the weight of each. With the cylinder head in place, the clearance space of the head end is to be filled from one vessel and a note made of the time required. As soon as the space is filled, the first vessel is to be set to one side for subsequently determining the weight of water thus used, and the clearance space is to be kept filled against leakage for five minutes by adding water from the second vessel. The vessels are then again weighed and the weight of water used from each determined.

The average rate of leakage while filling the space may be assumed to be one-half of the rate during the filling. If

W = Weight of water in pounds used to fill the clearance space,
t = Number of minutes required to fill the clearance space, and
w = The weight of water in pounds per minute necessary to keep the space filled against leakage,

then the leakage during filling is approximately $(W \times t) \div 2$, and the clearance space will contain $W - [(w \times t) \div 2]$ lb. of water and this multiplied by 0.036 will give the space in cubic inches. The clearance for the crank end of the cylinder is found in the same general manner.

The Storage of Bituminous Coal*

BY H. H. STOEK†

An unusually valuable paper on why coal should be stored; the practicability of storage and effect of storing on the coal; systems of storage employed; cost per ton, and precautions to be observed.

ALTHOUGH the storage of coal has become of unusual importance under war conditions, it should not be considered only as a war expedient, and plans for storage should be made by every householder and in connection with every industry that uses coal as one of the adjustments necessary to stabilize a fundamental industry of the country.

The demand for coal varies with the weather conditions and is largely a seasonal one, not only as regards domestic fuel, but in connection with fuel used for power purposes. As a result of the unequal requirements at different seasons of the year, and the failure to store coal during periods when small amounts are used, the mines of the United States operate only about 200 days per year and the demands upon the railroads for handling coal are unequally distributed, the greatest demand coming during the fall when railway equipment is needed for handling crops and during the winter months when operating expenses are greatest.

As a result of the reduced time of working of the mines, an extra daily wage must be paid the miner and other employees if they are to make a yearly living wage, and there must be also an excessive number of mines to take care of this peak load during a part of the year.

A reason often advanced against storage is the increased cost involved, but a suitable readjustment of mining and transportation conditions should mean a lower cost for mining and transportation that would, at least partly, offset the additional necessary cost for storage and should not increase the cost to the consumer much, if any.

STORAGE SHOULD ADD BUT LITTLE TO COST TO CONSUMER

The effect of storage upon coal may be considered under the heads of appearance, loss in heat value, difference in firing qualities of stored coal, change in coking properties, change in gas-making properties, and degradation, or the increase in the amount of fine coal and dust due to breakage from handling and the slacking or weathering due to exposure to the air.

With reference to appearance the exterior of a pile of certain kinds of coal frequently becomes covered with a white coating of sulphate of iron or it may be rusty and dirty in appearance. Usually, this change in appearance is only "skin-deep," and the interior is not changed in appearance to any extent, excepting with certain slack coals. Some coals have a much dirtier appearance in the piles after being in storage, and although the heating value is not reduced thereby the sale value may be decreased because, to the domestic user particularly, the appearance of the coal means much.

Loss in heat value, due to storage, is much less than is commonly thought. It varies with different coals and is greater for screenings than for screened coal. Experiments by Prof. S. W. Parr, University of Illinois, show a loss of only 3 to 3½ per cent. for screenings and also that coals vary in this respect. Those from southern Illinois show less change than those from central Illinois; also coals that show a small decrease at first continue to have only a small decrease as time goes on.

There is a general and widespread opinion that stored coal is dead when put on the fire and is often considered and condemned as being "no good." Although there is no great decrease in calorific power, it is quite probable that, due to the oxidation of the surfaces of the lumps of coal, they burn less freely, but experiments made at the University of Illinois on a stationary boiler showed that the stored coals tested had an equal evaporating power with the fresh coal, provided a thinner bed was carried and greater draft furnished.

SPONTANEOUS IGNITION OF STORED COAL

The greatest objection to storing coal is the liability to spontaneous combustion, which is due mainly to the oxidation of the carbon and other organic materials in the coal and to a less extent to the oxidation of the sulphur in the iron pyrites contained in most coals. Freshly mined coal has a tendency to oxidize and heat, and while this property varies with different coals, the general rule apparently holds for all coals. The finer the coal the greater the surface exposed to the air and the greater the tendency to oxidation and heating. Lump coal is not so likely to fire as fine coal, slack or run-of-mine. Any method of storage must either prevent or check the absorption of oxygen to such an extent that the generation of heat may not proceed so rapidly as to exceed the heat lost by radiation. The greater the time between mining and storing the less the liability to firing.

High-volatile matter does not increase the liability to spontaneous combustion, according to the experiments of Porter and Ovitz, of the Bureau of Mines. The high-volatile coals in the West are liable to spontaneous combustion, but Porter and Ovitz conclude that this is due more to the nature of the volatile than to its amount. Sulphur in coal assists in spontaneous combustion by oxidizing and breaking it up so as to produce greater fines, and also in its oxidation, heat is produced. In selecting a coal for storage a low-sulphur coal is to be preferred.

The effect of moisture on spontaneous combustion is an unsettled question, but it is undoubtedly safer practice not to wet coal for storage; if it can be avoided, do not store a layer of dry coal on a wet layer. The effect of water in helping to disintegrate high-sulphur coals is undisputed.

Data on the effect of storage on the coking properties of coal are scarce, but the general opinion is that unless the coal heats and thus changes in character, its coking properties are not materially influenced. According to the experiments of White, the gas-making qualities of Eastern coals are not decreased by storage.

There is often thought to be a loss in weight of stored coal, but this is more apparent than real and may be due to the evaporation of moisture.

NEARLY ALL COALS CAN BE STORED IF PROPERLY PILED

There is an erroneous, misleading but widespread opinion that the locality from which the coal comes determines whether or not it can be stored. One frequently hears such remarks as "Eastern coals" (meaning those from Pennsylvania and West Virginia) can be easily stored, but Western coals (meaning those from Illinois and Indiana) cannot be and they are much more liable to spontaneous combustion." Both parts of this statement are too broad, for scientific research and experience have shown that nearly any coal can be stored if it is properly piled and nearly any coal improperly stored will heat and may fire.

Coal should be stored preferably during the spring and summer so as to help the railroad and mining situations; labor costs are usually less. The disadvantage of summer storage is that the coal maintains this temperature for a long time.

The size, shape and depth of piles depend mainly upon the appliances used for storing. There is a great difference of opinion as to the height to which coal can be safely piled and stored. Many would limit the pile to 10 ft. in height,

---

*Abstract of paper read before the Western Society of Engineers, Chicago, April 15, 1918.

†Professor of Mining Engineering, University of Illinois.

although many dock piles are 50 to 60 ft. high, and the chief objection to high piles is the difficulty in handling and moving the coal quickly in case the temperature rises and also the difficulty of testing for an increase in temperature. The idea that firing takes place at the bottom of the pile due to the pressure and crushing on account of the height is not borne out by the facts, as many fires seem to start near the top as near the bottom and near the outside as the inside of a pile. Since the weight of a cubic foot of broken coal is about 40 lb., a column 50 ft. high weighs only 2000 lb., which gives a weight of only about 14 lb. per sq. in. at the bottom of the pile. This is small compared with the crushing strength of most coal even when it is considered that the coal does not rest on a solid base, but is supported in many cases on the points of the pieces of coal. Heating due to pressure is certainly overestimated, probably also pressure due to the weight of the overlying coal.

It is generally accepted that if the air supply is shut off from the coal, as is the case with under-water storage, spontaneous combustion cannot occur, and also it is reasonable to assume that if ample ventilation can be furnished to carry off the heat and keep down the temperature in a coal pile, spontaneous combustion will not occur. It is the intermediate condition that is dangerous. On the other hand, run-of-mine coal often cannot be safely stored, because not only is there then present an excessive amount of fine coal that will oxidize readily, but the openings between the lumps contain considerable fine coal, which shuts off a free circulation of air.

This also explains why alternate stratification of coarse and fine coal is undesirable and why air passages due to large lumps rolling to the bottom of the pile should be avoided, because they form a duct or chimney for an amount of air to reach the fine material inside the pile, sufficient to promote oxidation but insufficient to keep down the temperature.

VENTILATING A COAL PILE

The practicability of properly ventilating a coal pile has been disputed, and while the consensus of opinion in the United States is against ventilation by pipes, it is probable that many of the opinions expressed are based upon unfavorable results secured through improperly installed and inadequate ventilation schemes. Many of the so-called pipe ventilation schemes have been little more than the occasional placing of a pipe into which a thermometer can be inserted to read temperatures. There are few records in the United States of a systematic and adequate ventilation scheme being installed, because such a scheme is expensive and it also undoubtedly interferes with the rapid handling of the coal. It is contended by many that closely packed coal is so poor a conductor of heat, fire can start very close to a ventilating pipe.

Several instances of successful ventilation have been cited to the writer in connection with railroad work in the United States and Canada. Dr. J. B. Porter, of McGill University, is convinced that the method of ventilation used by the Canadian Pacific R.R. and others in Canada is efficient and entirely practicable. It is questionable whether the cooler climate of Canada has anything to do with the effective ventilation noted by Dr. Porter. Data upon this subject for Illinois conditions are certainly not yet conclusive, and ventilation is a questionable experiment.

The common methods for testing heating coal piles are: Watching when the pile begins to steam, the odor which is either that of burning bituminous matter or burning sulphur; by means of an iron rod inserted into the pile and when drawn out tested by feeling with the hand; by means of the thermometer inserted into a pipe driven into the pile; and by spots of melted snow.

Opinions differ widely in regard to when the temperature reaches a critical or danger point. Parr says, "Bituminous coal can be stocked without appreciable loss of heat value provided the temperature is not allowed to rise above 180 deg. F." How close to this temperature a pile should be allowed to heat is largely a matter of judgment, for if the rise seems to be decreasing rather rapidly, it may be safe to allow it to approach the 180-deg. point; but if it is steady and regular, it is wise to load out the pile before the danger point is reached. This rise also depends upon the means available for loading out, for at a point equipped with large grab buckets and means for rapidly handling the coal, a higher temperature can be permitted than when considerable time may be required to load out the coal. A person in charge of a certain kind of coal under certain climate conditions will soon learn what is the danger point, and it is impossible to set any critical temperature that will apply to all coals under varying storage conditions. The only safe rule is to watch the temperature closely and get ready to load out when the temperature reaches 150 deg. and to move the coal if the temperature reaches 175 degrees.

WATER NOT EFFECTIVE IN PUTTING OUT FIRES

Water generally has not proved effective in putting out fires, probably because it cannot be applied or is not applied in sufficient quantities to thoroughly cool the entire mass. It is the general opinion that except for quite small piles which can be completely soaked, water will aggravate rather than put out a fire. Water frequently cannot reach the fire because of a layer of coke that has formed a protection about it. One large pile in Chicago was soaked as completely as possible with streams from river fire tugs, and while the fire was apparently out, within two or three days it was burning as fiercely as ever. If the coal can be spread out thinly and thoroughly saturated with water, the fire can be put out, but very often there is not sufficient ground available to permit proper spreading, for which reason most of the efforts to use water have been unsuccessful.

Inert gases, such as carbon dioxide, have been tried, but no successful results have been reported, because with an outdoor pile it is impossible to confine such gases, and even with inclosed piles where this has been tried, the same difficulty has been met with.

The author enumerated the points to be considered in the choice of a storage system and the requirements of an ideal plant. Following, brief descriptions were given of the principal methods of storing, such as hand storage, storage by means of a motor truck, trestle storage, storage with side-dump cars, side-hill storage, mast-and-gaff storage, locomotive-crane storage, circular storage, steeple storage, bridge storage and under-water storage. For more complete details reference was made to the speaker's paper on "Storage of Coal," Circular No. 6, Engineering Experiment Station, University of Illinois, Urbana.

LOCOMOTIVE CRANE STORAGE

Under the heading of "Locomotive Crane Storage," reference was made to the practice of the Commonwealth Edison Co., of Chicago, and the following conclusions by W. L. Abbott based upon storage of all varieties of Illinois coal over long periods:

"Nearly any coal that has gone over a 1½-in. screen can be stored. Coal of any size with duff left in it will heat.

"Pea coal (over ½-in. through ¾-in.) has been in storage for more than a year without heating. Coal with screenings removed has been kept in storage eight years without firing."

The coal is stored on the ground in continuous pyramidal piles 25 ft. high, each pile being between two pairs of railroad tracks.

Cost figures for storage and reclaiming from a number of different companies were presented. Some of the figures given include only labor and supplies, with no allowances for overhead, insurance, rental for the land, depreciation and interest on the investment. For hand storage the cost per ton varied from 15 to 64 cents; with the locomotive crane, from 5 to 50 cents; with the steam shovel, 20 cents; with bridge storage, 11 to 60 cents; and with under-water storage, 9 to 22.5 cents.

As the result of a rather detailed study of a number of storage plants and as a digest of the opinions expressed in answer to a questionnaire sent to a large number of those who have had extended experience in storing coal, the following have been decided upon as conclusions that are justified by present storage practice:

It is practicable, advisable and advantageous to store bituminous coal not only during war times, but also under normal conditions either at the mines, near the point where it is to be used, or at some intermediate point. It is well to store coal as near the point of consumption as possible to avoid rehandling.

The danger from spontaneous combustion is due more to improper piling of coal than it is to the kind of coal stored. Most varieties of bituminous coal can be stored in the air if of proper size and if free from fine coal and dust. The coal must be so handled that dust and small coal are not produced in excessive amounts during the storing, because spontaneous combustion is due mainly to the oxidation of the coal surface.

All varieties of bituminous coal can be stored under water, which excludes the air and prevents spontaneous combustion.

The danger of spontaneous combustion in storing the coal is greatly reduced if not entirely eliminated by storing only lump coal from which the dust and fine coal have been removed. Of two coals the less friable should be chosen for storage.

Spontaneous combustion may be guarded against by preventing air currents through the pile by means of a closely sealed wall built around the pile, and by closely packing the fine coal. Such a coal pile must be closely watched for heating. The only absolutely safe way to store slack or fine coal is under water.

Fine coal or slack has sometimes been successfully stored. Many varieties of mine-run coal cannot be stored safely because of fine coal and dust mixed with the lumps.

Coal exposed to the air for some time may become "seasoned" and thus may be less liable to spontaneous combustion, due to the oxidation of the surface of the lumps of coal, but opinions upon this point are not unanimous.

It is believed by many that damp coal stored on a damp base is peculiarly liable to spontaneous combustion, but the evidence is not conclusive.

Air Should Circulate Freely Through the Coal

To prevent spontaneous combustion coal should be so piled that air can circulate through it freely and thus carry off the heat due to oxidation of the carbon, or else it should be so closely piled that air cannot enter the pile and oxidize the fine coal.

Stratification or segregation of fine and lump coal should be avoided since an open stratum or a chimney of coarse lumps of coal gives a passage for air to enter and come in contact with fine coal and thus to oxidize it and start combustion.

If space permits, low piles are preferable.

Coal of different varieties should not be mixed in storage if this can be helped, for one coal more susceptible to spontaneous combustion than the other may jeopardize the safety of the pile.

The heating value of a coal is decreased little by storage, but the belief is widespread that storage coal burns less freely when fired in a furnace. Experiments indicate that much of this can be overcome by keeping a thinner bed on the grate than is kept with fresh coal and by regulating the draft.

Pieces of wood, greasy waste or other easily combustible material mixed in a coal pile may form a starting point for a fire, and every effort should be made to keep such material from the coal as it is being put in storage.

J. L. Hecht, mechanical engineer of the Public Service Co. of Northern Illinois, never had a fire in a storage pile of lump coal; that is, coal that had been screened. No attention had been paid to the height of the pile except from the standpoint of convenience of handling. The company never stored screenings, but had stored No. 3 nut coal for three or four years without signs of heating.

Screenings had been stored successfully at the University of Illinois by packing the fuel closely and excluding the air as much as possible. Coal from a truck was dumped on a former tennis court, which offered a hard foundation. When the fuel reached a certain height, it was smoothed over and pressed down into a compact mass by means of rollers. Plank roads were then laid on the pile so that the truck could distribute another layer of coal and this in turn was rolled down as before. To prevent air circulation from the sides, a board fence surrounded the pile. Heating developed in a couple of places where other coal had been mixed with the screenings, but otherwise this method was satisfactory. The cost for storing and reclaiming had averaged about 40c. per ton.

James Macdonald, president of the Macdonald Engineering Co., had developed, for a plant in Michigan, a vertical method of storage, which appeared to possess advantages over the various horizontal plans universally used. He was a firm believer in the exclusion of air and this was effected in the present case by storing the coal in two vertical reinforced-concrete tanks resembling the farm "silo." The tanks were 28 ft. diameter by 70 ft. deep. Depending upon the foundation, it was easy to vary the dimensions to suit the requirements. The storage was fireproof, occupied little space and was convenient to the power house. Slack coal had been stored so successfully that a duplicate installation was now being made. In case of heating, conveyors had been provided so that the bottom coal could be removed and transferred to the top and water pipes had been laid so that the tanks could be flooded. Neither of these precautions had to be used as the coal never fired.

Weights and Measures in Venezuela

The use of the metric system in all business transactions is not only legal but compulsory throughout Venezuela. The law of Feb. 13, 1857, prescribed that, beginning Jan. 1, 1858, the metric system should be used in all the government offices and for all public acts, and that a year later it should be used by all Venezuelans. Evidently the last-named proviso was not enforced for the old system of weights and measures continued in almost universal use among the people until the issuance of the decree of May 18, 1912, which was based on the old law and took rigorous steps to put it into effect. Under date of Feb. 13, 1914, the Federal Executive prescribed rules for the use and practice of the metric system. A pamphlet was published in Caracas in 1916 under government auspices and shows in detail the steps that have been taken to make the use of the metric system compulsory and to uproot the old methods which had survived.

The strict measures taken have compelled the adoption of the metric system for all business transactions of any importance. Not only is it illegal to use any other weights and measures, but a merchant is subject to punishment even for having them in his possession. The use of units indicating another system in addition to the metric is also illegal. The importation of weights and measures other than the legal is prohibited, and as the authorities have destroyed the old ones wherever possible, distinct progress toward the universal adoption of the new system has been made.

In spite of the stringency of the laws, the people at large, especially in the country, still cling to old units in their everyday life and talk and think in terms of them. This will only be finally remedied by the growing up of a new generation.

The units of weight and measurement formerly in use in Venezuela were varied as well as variable. Many of the measures differed according to the article and the locality. Thus the fanega, which was widely used, and for much the same purposes as in the bushel in the United States today, weighed from 110 to 864 lb., depending on the product measured and the locality concerned. The quintal of 100 Spanish pounds, equivalent to 101.4 English pounds, was formerly much employed in the sale of coffee, cocoa and other products; and this usage still survives, although the transactions are officially reported as "per 46 kilos," which is the equivalent of the quintal.

It is generally agreed here that the compulsory adoption of the metric system was a wise measure and that its use has simplified and facilitated the transaction of business.—*Commerce Reports.*

A little more care in cutting out gaskets from sheet packing will make a big saving in that commodity. It is time that more attention was paid to this important, if minor, detail.—*Marine Engineering.*

National Coal Conference

Under the auspices of the United States Railroad Administration and the United States Fuel Administration the International Railway Fuel Association held its tenth annual convention in Chicago on May 23 and 24. Hotel Sherman was headquarters for the convention, and the meetings were held at Cohen's Grand Opera House. Upward of 1500 attended, including mine operators, representatives of the mine workers, railway executives and employees, railroad and fuel administration representatives and heads of industries that make large demands on fuel and transportation. It was an enthusiastic meeting, held with a view of bettering the coal situation, to impress on each factor the necessity for maximum efforts and the need for coöperation. Those attending were pledged to carry home the spirit of the meeting and inspire the vast army of workers responsible for results. Nearly a million copies of the proceedings will be distributed to these men.

Expressing the sentiments of those addressing the convention, American miners must get out more and cleaner coal. American railroad men must furnish the locomotives and the cars to haul it, and in their use of fuel must make every pound count. The consumer can also do his part by ordering now to relieve the situation later on. It was made apparent that there was no lack of miners and that if they were employed full time as in other trades, there would be no coal deficiency.

In his opening address E. W. Pratt, president of the Association, summed up the railroad coal problem as one of hauling more coal with fewer cars. It was a question of doing the maximum amount of work with the facilities at hand. Regional Director Aishton, of the United States Railroad Administration, declared that the only thing that mattered for all of us now is the maintenance of that line "over there." He begged the miners and railway men of America to "strip to the waist" and do their utmost to help maintain that line. Trooper Scott, of the Anzacs, told how he pleaded with the coal miners to supply the fuel to win the war, and how when they realize what their work means, they go to it harder than ever to increase the output. His plea to the miners was, "Load all the coal you can and load it clean."

Thomas Britt, general fuel agent of the Canadian Pacific Ry., spoke for Canada, emphasizing the importance of coal loaded clean and free from slate, dirt or other nonburning substances. Troopships burning dirty coal are slowed down in the U-boat zone, doubling the danger of the thousands of soldiers carried to the front.

R. Quayle, general superintendent of motive power and car department of the Chicago & Northwestern Ry., urged that every man make it a personal matter to cut out waste of coal in railway operation. In a paper prepared by W. S. Carter, labor director of the United States Railroad Administration, and read by Eugene McAuliffe, it was stated that in the spring of 1919 American railroads must be ready to haul cargo and bunker coal for 8,000,000 tons of army shipping, supplying 2,000,000 American troops in France. This, in addition to the present great fuel demand, would necessitate that the eight-hour work day, desirable in peace, yield to the Nation's need, and that railway men must prepare to work as many hours as the job may call for up to the limit of their power. Better maintenance of locomotives as a means of saving coal was urged by Frank McManamy, director of the locomotive maintenance division of the United States Railroad Administration. It was estimated that defective and neglected motive power would cost the American railways this year $50,000,000 worth of coal, besides the great loss of efficiency.

On Thursday evening the feature was a motion picture dealing with the conservation of railway fuel. The picture had been prepared by and under the direction of the United States Fuel and Railroad Administrations and was viewed with a great deal of interest by those in attendance.

At the opening session Friday, P. B. Noyes, director conservation division, United States Fuel Administration, said that it was impossible for the railways, with their burden of war traffic, to haul the 200,000,000 tons of coal in excess of the requirements of 1914, that will be needed this year. Coal users must save the situation by saving coal, or the country would suffer a disastrous stoppage of industries. The Fuel Administration would try to keep the non-war industries supplied with coal, because these are the vital industries of peace, and their serious interruption would cause a nation-wide commercial panic. At least $20,000,000,000 of capital is invested in legitimate manufacturing enterprises not strictly needed for the war. Ten million men support their families from the work they do in these factories. Cutting off their fuel supplies would mean bankruptcy on a scale that would precipitate the greatest panic ever seen in the United States, and the sudden and forcible unemployment of at least 5,000,000 men. All responsible agents of the Government now realize that keeping labor reasonably employed and only taking it away from non-war work as fast as it can be employed on war work is nearly as important for success in this war as the manufacture of munitions and ships.

Peace in American coal fields for the duration of the war was pledged for miners and operators by John P. White, former president of the United Mine Workers of America, and now labor advisor for the United States Fuel Administration. He declared that 700,000 American coal miners were eager to work every day, Sundays and holidays, getting out the extra 200,000,000 tons of coal needed this year. It was a question of the railways furnishing the cars and the consumers placing their orders so that consecutive employment in the mines would be possible. Mr. White said that the 87,000 miners of Illinois alone, who work on the average only 160 days per year and mine 60,000,000 tons of coal, could get out 150,000,000 tons of coal this year if enabled to work full time. If the railroads would quit haggling over price and start buying their coal, everybody else would follow suit, production would rise and there would be no coal famine next winter. The one big mistake that had been made was in talking price instead of production.

H. N. Taylor, of Kansas City, a big coal operator, won hearty applause when he agreed with Mr. White that if the country had a coal shortage next winter, it would not be due to a wage war in the coal field. The mine operators have been hampered by loss of men and the wearing out of machinery which could not be replaced or repaired. They have to make the best efforts they can with what they have. The consumer has not wakened up to his responsibilities. Most of the coal mines in the Central West and the Southwest are working only half time, because the large buyers are holding back for a lower price. There is need of coöperation and coördination among the operators, the miners, the railway men and the consumers. Last year there was a shortage of 50,000,000 tons of bituminous coal. Even to keep even with last year, this much extra coal must be mined. The operators could produce it if the necessary cars were available. There are two ways of increasing the coal output: One is to produce more coal and the other to save coal. If maximum results are obtained from both there will be no coal shortage.

Eugene McAuliffe, manager of the fuel-conservation section of the United States Fuel Administration, intimated that the Government might find it necessary to take over the coal mines for the period of the war. According to Claxton E. Allen, deputy fuel administrator for Illinois, records of all coal sales are being kept, so that if necessary the administrator can take coal from those who have a surplus and allot it to others who have none.

"Fuel Oil and the War" was discussed in a paper sent by M. L. Requa, director of the oil division of the Fuel Administration. Diversion of all tankers from coastline to transatlantic army-supply service required the railways to haul an extra 100,000 bbl. of oil a day from Southwestern fields to the north Atlantic war industrial centers. Pipe-line deliveries are to be increased by 20,000 bbl. daily and the maximum number of tank cars have been placed in service. Fuel-oil users are urged to increase their storage capacity and lay in as much of their winter supply as possible before the summer is over.

The convention closed Friday afternoon with a business session at the Hotel Sherman, at which the following officers were elected: President, L. R. Pyle; vice presidents, C.

M. Butler, H. B. MacFarland and J. B. Hurley; members of executive committee for two years, B. Pemberton Phillippe, A. N. Willsie, T. Duff Smith and R. R. Hibben; members of executive committee for one year, H. B. Brown, L. J. Joffray and H. Woods.

Joint Meeting of the Chicago Section A. S. M. E. and W. S. E.

Officially, the last meeting of the season for the Chicago Section of the A. S. M. E. was held Friday evening, May 24. It was a joint dinner meeting with the Western Society of Engineers, held at the Hotel La Salle. Notwithstanding, another joint meeting will be held on June 17 at the rooms of the Western Society, the topics being "Modern Condensers" and "The Benefits To Be Obtained in the Power Plant from High-Pressure and High-Temperature Steam."

Preliminary to the paper of the evening, the question of training women for drafting work was brought up and resulted in arrangements for a meeting between educational sources and business men to see if such help was needed in this section and the possibility of introducing suitable courses. It developed that Armour Institute had already established a short intensive course to train women for drafting work.

Calvin W. Rice, national secretary, was a welcome visitor. His presence was explained as a continuation of the plan for the national officers to visit the local sections to relieve the impression that the organization is local to New York and not national in its interests. Mr. Rice had made an extended trip and had been impressed with the advance in thought among engineers. He had been particularly impressed by the motto of the new Engineers' Club at Dayton, Ohio. The speaker wanted to see coöperation between national and local bodies and between the various societies. Each engineer should do something altruistic and make the profession an instrument for the common good. He wanted to see engineers identified with the Board of Trade or similar bodies. They must be good citizens and help guide civic matters, but as a body should not take sides in politics. At the present all meeting topics should relate in some way to the war, so that in its winning, the services of the engineering societies would be preëminent.

In his retiring address President Bailey expressed the opinion that the best thing the executive committee of the section had arranged for during the past year was the joint meetings. They had proved a decided success and should be continued. The new officers elected were: Chairman, G. E. Lord; vice chairman, P. A. Poppenhusen; secretary, A. L. Rice; member of executive committee, J. J. Merrill.

John Ericson, city engineer, reviewed the construction of the Wilson Avenue tunnel and the Mayfair pumping station. The tunnel, which is eight miles long from the crib in the Lake to Mayfair pumping station, has been completed successfully and at a big saving by day labor. The finer sections of the stone removed from the tunnel were used in the concrete lining it. By the use of special screening and conveying machinery, the concrete was mixed in the tunnel, and it had not been necessary to follow the usual procedure of removing the stone from the tunnel and then taking it back again for the concrete. Excavation and lining were carried on simultaneously.

The design and erection of the intake crib, specially designed by the city, were discussed and the equipment of the station outlined. It was laid out for seven units, but only five have been contracted for. Three were designed for a head of 140 ft. and two for a head of 200 ft. The capacity of each of the former units is 25 million gallons and of the latter 17.5 million gallons per 24 hours. The pumping engines are of the Reidler triple-expansion type employed at the Lakeview Station. Six boilers equipped with underfeed stokers have been provided. The operating pressure is to be 190 lb. gage and the superheat 200 deg. Complete coal- and ash-handling facilities are being installed. It is the tenth large pumping station built for the City of Chicago. The estimated cost is $1,570,000, and that of the tunnel $3,856,000, so that the total cost of the system will approximate $5,426,000.

Price of Bituminous Coal Reduced

For a long time there has been a difference of opinion between the Fuel Administration and the Railroad Administration as to the price of coal to the railroads. By agreements with certain mines the railroads had been obtaining their coal at prices much lower than those to other consumers. The dispute has been settled conclusively by an order of the President, effective on May 25, 1918, by which the price of bituminous coal is reduced 10c. a ton and the railroads are forced to pay the Government price. The text of the order is as follows:

The United States Fuel Administration, acting under authority of an executive order of the President dated Aug. 23, 1917, appointing said Administrator, and of subsequent executive orders and in furtherance of said orders and of the act of Congress therein referred to and approved Aug. 10, 1917, hereby orders and directs that all prices for bituminous coal f.o.b. mines in the coal-producing districts throughout the United States fixed by the said executive order of the President, dated Aug. 21, 1917, and subsequent orders of the United States Fuel Administrator, and in effect at 7 a.m. on the 25th day of May, 1918, shall be and the same hereby are reduced as to all shipments made after 7 a.m. on the 25th day of May, 1918, by the sum of 10c. for each net ton of 2000 pounds.

This order shall in no way affect the increase contained in the executive order of the President dated Oct. 27, 1917, adding the sum of 45c. to the prices fixed for bituminous coal under the terms and provisions set forth in said last-mentioned order.

Regarding this order, the Fuel Administration has issued the following statement:

The reduction will mean an annual saving to consumers of a sum estimated by the Fuel Administration at $60,000,000. The President has directed that the railroads pay the Government price for coal. The increased cost of railroad fuel thereby occasioned is also estimated at $60,000,000 per annum. The reduction of 10c. per ton on all coal will, however, reduce the net increased cost to the railroads from $60,000,000 per annum to $45,000,000 per annum. Under the President's plan the railroads will furnish cars to all coal mines alike, without discrimination except as dictated by the prior requirements of the railroads for operating purposes and the needs of domestic consumers and of the war.

Under the present war demands the maximum output of every mine working at full time would still be insufficient to meet the country's coal needs. The principle of equal car supply has accordingly been adopted so as to make for as steady an operation as possible of all properties and for continuous employment of men, thus making for maximum output.

The introduction of the principle of even car supply will reduce the general average overhead of mine operation and thereby justifies the Administration in putting out a price reduction order. It is understood that the mine prices thus fixed will remain undisturbed until the United States Fuel Administrator has before him the cost returns for the twelve months ending Aug. 31, 1918.

The returns thus far in are being carefully studied by Fuel Administration accountants and engineers, with a view to making the utmost saving to the public that is consistent with a maximum production of coal.

The order issued tonight will have no effect on the price of anthracite, which forms the bulk of the domestic consumption fuel in the eastern part of the country.

Consumers of bituminous coal who have already entered their orders for the year's coal supply, but whose coal has not yet been delivered, will, of course, receive their supplies at the reduced price. This price applies to all coal which leaves the mines after 7 a. m., May 25, no matter how long the order for the delivery of the coal has been standing.

Coal delivered after 7 a. m., May 25, under contracts which have been entered into since Dec. 29, 1917, will be billed at the new price. Under the regulation of the Fuel Administration all such contracts call for the delivery of coal at the Government price effective at the time of delivery.

Organizing a Division of Inspection To Insure Clean Coal

To guard against the waste and serious loss resulting last winter from the shipments of dirty coal, which occupied car space and also seriously decreased industrial-plant efficiencies, the Fuel Administration has organized a division of inspection, with C. M. Means as manager. A chief inspector has been appointed in each of 21 representative districts, and where necessary assistant inspectors will be added. These inspectors will examine coal in the mines, also as dumped from mine to tipple, watch the picking tables and again inspect the coal as it is loaded in cars for shipment.

Standards will be established for insuring proper preparation according to use, so that all coal shipped must be of the quality required for its particular purpose. By condemning coal at the mine, a great improvement in the transportation situation should result in that the railroads will in effect be hauling heat units, not ash. Miners who get out dirty coal will be penalized, and a bonus system is being developed. Mines that cannot supply properly prepared coal will not be allowed to ship by rail.

Committee Studying Potomac River Power Project

A committee consisting of Brig. Gen. W. L. Marshall, chairman, Reclamation Service, Department of the Interior; Col. H. C. Newcomer, Corps of Engineers, War Department; A. L. Parsons, Bureau Yards and Docks, Navy Department, and Nelson S. Thompson, Supervising Architect's Office, Treasury Department, appointed several weeks ago, is making a study of the data at hand looking to the development of power from the Potomac River to supply electric current for various Federal and municipal uses. Two tentative plans have been prepared by Mr. Thompson. One involves building a large dam between the hills above Great Falls and conducting the water to a point near the Chain Bridge, where a fall of 180 ft. could be obtained. The estimated cost is about $40,000,000. The other plan—to build two smaller dams, one above Great Falls and another near Chain Bridge—would cost about half as much as the first plan, but would involve flooding considerable inhabited area and relocating the Chesapeake & Ohio Canal at this point.

Any plan must, however, take into consideration the water supply for the district, with its ever-increasing demands, taken from the Potomac at Great Falls. This was originally a gravity system built by and under the control of the War Department. The development of the city toward the northwest, higher ground, and the completion of a filtering system in recent years have made pumping necessary. A special report by Colonel Fiske, engineer in charge of the District water-supply system, points out the necessity for an increased water supply on account of the increased population and industrial activity. The problem therefore becomes more complicated than the usual water-power or water-supply project alone.

University of Illinois, Summer Session

The 1918 Summer Session of the University of Illinois will offer special advanced courses planned especially for instructors in mechanics in trade schools and technical schools, for chemists who wish to fit themselves to take positions involving the physical testing of materials, and for men who wish to fit themselves for positions in commercial or Government testing laboratories. Three special courses will be offered:

1. Advanced Mechanics of Materials. Advanced problems in strength of materials. A knowledge of elementary mechanics of materials is a prerequisite for this course.

2. The Properties of Engineering Materials. Lectures and assigned reading on the properties of iron, steel, other metals, wood, brick and concrete. A knowledge of elementary mechanics is a prerequisite for this course.

3. Laboratory Work in Testing Materials. Study of testing machines and strain-measuring apparatus; practice in standard methods of testing and tabulation of test results. A course in elementary mechanics of materials accompanied by work in the laboratory is a prerequisite for this course.

The extensive equipment of the materials testing laboratory of the university will be available for this work, which will be under the direct charge of H. F. Moore, research professor of engineering materials. Further information concerning the courses and expenses may be obtained from the Director of the Summer Session, University of Illinois, Urbana, Illinois.

Personals

W. V. Houck has tendered his resignation as works manager with the Sterling Engine Co. to accept a factory managership, and also an interest in the Buffalo Metal Goods Co.

Julius Alsberg has opened consulting engineering offices in the Tribune Building, 7 S. Dearborn St., Chicago. He is prepared to make investigations and reports on mechanical, industrial and chemical engineering problems, to design plants and to supervise their installation.

Robert L. Brunet, for the last five years public-service engineer of the City of Providence, R. I., and previously power engineer of the Essex Division, Public Service Corporation of New Jersey, has resigned from the former to become industrial and efficiency engineer of the Jenckes Spinning Co., Pawtucket, R. I.

Engineering Affairs

Universal Craftsmen, Council of Engineers, will hold its sixteenth annual convention at Detroit, Mich., August 5-10, with headquarters at the Statler Hotel. This is to correct error on page 642, April 30 issue.

New York State Convention N. A. S. E., will be held at Coney Island, Brooklyn, June 14-16, with headquarters and exhibits at the Shelbourne Hotel. Upwards of 60 booths have already been sold, and there is every promise of a successful meeting. Brothers McGowan, Casey, Downey and Cole are members of the hustling arrangement committee.

American Order of Steam Engineers will hold its annual meeting at Philadelphia, June 11-13. The meetings of the delegates will be held in the Parkway Building on Broad St. Because of the unsettled conditions, the display will be limited to a table exhibit. A large room has been provided for the get-together of the engineers and supplymen.

The National License Law Committee of the National Association of Stationary Engineers has had drafted and printed in pamphlet form a model state license law, as well as a set of instructions explaining and drafting a license measure. Information concerning these may be obtained by addressing the secretary of the Committee, F. W. Raven, at 417 So. Dearborn St., Chicago, Ill.

The Trustees of United Engineering Society at the regular meeting held May 23, elected the following men to the Engineering Foundation Board: Calvert Townley, of Westinghouse Electric and Manufacturing Co., New York, succeeding Gano Dunn. The following are additional members: Silas H. Woodard, Consulting Engineer, M. Am. Soc. C. E.; Dr. Joseph W. Richards, Professor of Metallurgy, Lehigh University, South Bethlehem, Penn.; Dr. David S. Jacobus, Advisory Engineer, Babcock & Wilcox Co., New York; H. Hobart Porter, of Sanderson & Porter, Consulting Engineers, New York.

The American Institute of Electrical Engineers at its annual meeting held in New York on Friday, May 17, elected the following officers for the administrative year beginning Aug 1, 1918: President, Prof. Comfort A. Adams, Harvard University, and Massachusetts Institute of Technology, Cambridge, Mass. Vice presidents, Allen H. Babcock, San Francisco, Calif.; William B. Jackson, Chicago, Ill.; Raymond S. Kelsch, Montreal, Quebec; F. B. Jewett, New York City; Harold Pender, Philadelphia, Penn.; John B. Taylor, Schenectady, N. Y. Managers, G. Faccioli, Pittsfield, Mass.; Frank D. Newbury, Pittsburgh, Penn.; Walter I. Slichter, New York City. Treasurer, George A. Hamilton, Elizabeth, N. J. These officers together with the following holdover members, will constitute the Board of Directors: E. W. Rice, Jr., Schenectady, N. Y.; H. W. Buck, New York City; C. E. Skinner, East Pittsburgh, Penn.; John B. Fisken, Spokane, Wash.; N. A. Carle, Newark, N. J.; Charles S. Ruffner, St. Louis, Mo.; Charles Robbins, East Pittsburgh, Penn.; E. H. Martindale, Cleveland, Ohio; Walter A. Hull, West Lynn, Mass.; William A. Del Mar, New York City and Wilfred Sykes, East Pittsburgh, Penn.

Miscellaneous News

Coal Production Slightly Increased—The report of the United States Geological Survey on coal production for the week ended May 11, shows the bituminous yield to have been 11,806,000 net tons, which was an increase over the preceding week of 252,000 tons, or 2.2 per cent. The anthracite production declined during the week more than 5 per cent. The shipments amounted to 38,314 carloads, as against 40,570 carloads during the previous week.

Big Turbine for New York City—The United Electric Light and Power Co., of New York City, has recently placed an order with The Westinghouse Electric and Manufacturing Co. for a 22,000-kw. turbo-generator set. The generator will be rated at 25,900 kv.-a., at 85 per cent. power factor, 8000 volts, three-phase 62½ cycles. It will be direct-connected to a Westinghouse 22,000 turbine. The order includes a 40,000-sq.ft. surface condenser and the usual auxiliaries.

Must Keep Oil Prices Steady—A communication just issued by the Oil Division of the United States Fuel Administration warns oil producers that the Government will not at this time view with approval any further advance in the price of crude oil. Competition in the form of payment of bonus is also to be restrained. By this it is not meant that varying prices should not be paid for oils of varying quality, but these differentials once established should not be further advanced.

The Penberthy Injector Co. is offering to stationary engineers' associations an artistically framed photograph showing the interior construction of their automatic injector, on which also is given a complete and concise explanation of its working. This should be of exceptional educational value and when hung in the association room it will be a permanent answer to the question, "Why does an injector work?" We suggest that the secretary of each association write at once to the Penberthy Injector Co., Detroit, Mich., for the photo, assuring them that it will be hung in the local rooms.

NEW CONSTRUCTION

N. Y., Black River—The Northern New York Utilities Co., 137 Arsenal St., Watertown, plans to build a plant on the Black River here, for the development of power. Estimated cost, $500,000. J. Brownell, Strickland Block, Carthage, Engr.

N. Y., Broadalbin—The Broadalbin Knitting Co. will soon receive bids for the erection of a 3-story, 75 x 100 ft. mill. Estimated cost, $65,000 Equipment, including electric motors, pumps, etc., will be installed. H. S. Moul, Gloversville. Arch.

N. Y., Fairport—A. S. Crocker, Engr., Mechanics Institute, Rochester, will receive bids until June 11, for the erection of a 2-story, 100 x 125 ft. factory and power plant here for the Douglas Packing Co., John St. Estimated cost, $25,000. Power equipment will be installed.

N. Y., Jamestown—The Art Metal Construction Co., Jones St. and G Ave., has had plans prepared by F. A. Shoemaker, Engr., Builders Ex., Buffalo, for remodeling and extending its boiler house.

N. Y., Olean—J. A. Coffey, Secy. Board of Armory Commission, 158 State St., Albany, will receive bids until June 12, for the installation of a complete heating system in its proposed 2-story, 52 x 110 ft. armory. Total cost, $100,000.

N. J., Gloucester City—The Pussy and Jones Co. plans to build a new electric power plant to supply power to several large shipbuilding plants.

N. J., Pompton Lakes—The City has had plans prepared by S. Firestone, Engr., Granite Bldg., Rochester, N. Y., for the erection of a hydro electric plant here. Estimated cost, $45,000. Noted May 7.

N. J., Trenton—The City plans to install 2 new pumps with generators for pumping station with 30,000,000 and 10,000,000 gal. capacity respectively. Estimated cost, $100,000. J. R. Fell, 134 North Clinton Ave., Engr.

N. J., Verona—The Board of Education will soon award the contract for the installation of a power and heating system in its proposed 4-story brick school on Laning Ave. Guilbert & Betell, 665 Broad St., Newark, Arch.

Penn., Greenville—Mercer Co. Commissioners are contemplating the erection of a brick power plant to be used for heating purposes. Plans include the installation of two 150-hp. boilers, a pump, etc.

Penn., Philadelphia—The United States Government has received bids for the erection of a 1-story, 57 x 154 ft. aircraft factory on League Island. A steam heating plant is to be installed in same. Estimated cost, $20,000. Noted May 28.

Md., Baltimore—The Maryland Creamery Co., 1726 East Pratt St., plans to build a 4-story, 50 x 90 ft., reinforced concrete, steel and brick ice manufacturing plant and cold storage building. Estimated cost, $55,000.

Va., Fieldale—The Caroline Cotton and Woolen Mill Co. is having plans prepared by F. P. Sheldon & Sons, Arch., Industrial Trust Bldg., Providence, R. I., for the erection of a weave shed and spinning mill. Motors, etc., will be installed.

Fla., Pompano—The Cypress Creek Lumber Co., Ft. Lauderdale, recently incorporated with $30,000 capital stock, plans to build a plant here. New machinery including power equipment, etc., will be installed.

Ohio, Cincinnati—The Dixie Terminal Co., 1st Natl. Bank Bldg., will purchase a battery of 200-hp. boilers for the main building to be constructed on 3rd St.

Ohio, Minster—The City will soon receive bids for the erection of a 1-story, 50 x 70 ft. power plant. Estimated cost, $50,000. V. I. Gray, 518 Nasby Bldg., Toledo, Engr.

Ind., Jeffersonville—The Quartermasters Dept., Wash., D. C., plans to appropriate $50,000 for a hospital, water pumping plant and an electric power plant here.

Ind., Maryland—The Evansville Tool Co., 9th Ave. and West Maryland St., Evansville, is having plans prepared by C. Brossman, Engr., 1618 Merchants Bank Bldg., Indianapolis, for the erection of a 1-story, 45 x 65 ft. power house. F. Lohoff, Evansville, Pres.

Wis., Depere—The Depere Manufacturing Co. has had plans prepared for the erection of an addition to its boiler works. Estimated cost, $35,000. E. S. Clark, Mgr.

Wis., Whitewater—The State Board of Normal Regents, Madison, plans to build a heating and power plant here. J. H. White, Madison, Engr.

Minn., Glen Lake—Sund & Dunham, Arch., 514 Essex Bldg., Minneapolis, will receive bids until May 31, for a built-in refrigerator and machinery for same at the Hennepin Co. tuberculosis sanitarium.

Minn., St. Paul—The State Board of Control will receive bids June 1, for the erection of a 2 story, 36 x 46 ft. power plant and laundry for the Home of Crippled Children, Phalen Park. Estimated cost, $40,000. New equipment will be installed. C. L. Pillsbury Co., 805 Metropolitan Life Bldg., Minneapolis, Engr.

N. D., Pembina—The Board of Education will receive bids until June 11, for the installation of a heating system, etc., in the grade and high school here. W. D. Gillespie, Fargo, Arch.

Penn., Philadelphia—The Bellevue Worsted Mills, Wister and Reading Rds., has awarded the contract for the erection of a 1-story, 30 x 89 ft. brick power house at 16th and Huntington Park Ave., to W. E. S. Dyer, Land Title Bldg. Estimated cost, $10,000.

Penn., Philadelphia—The Bureau of Yards and Docks, Navy Dept., Wash., D. C., has awarded the contract for the erection of a power house and 2 transformer houses to T. Riley, Philadelphia. Estimated cost, $130,078.

Md., St. Helena—The U. S. Shipping Board, Housing Division, Wash., D. C., has awarded the contract for the erection of a power house, bakery, etc., to the Consolidated Eng. Co., Calvert Bldg., Baltimore. Estimated cost, $800,000.

Ill., Chicago—The Fleischman Co., 427 Plum St., Cincinnati, Ohio, has awarded the contract for the erection of a 4-story, 62 x 85 ft. steel and brick factory. Estimated cost, $90,000. A new boiler and refrigerators are to be installed.

Ill., Chicago—Wilder & Co., 228 West Lake St., has awarded the contract for the erection of a 5-story, 50 x 125 ft. leather factory on Hawthorne St. Additions to the present steam heat and power plants will be built. Total cost, $75,000.

Que., Montford—The Montford Orphanage has awarded the contract for the erection of a hydro electric plant here, to Arsenault & Plamondon, 70 St. James St., Montreal. Estimated cost, $15,000.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular Current	Individual Current
Buckwheat	$4.60	$7.10—7.35
Rice	4.10	6.65—6.90
Boiler	3.90	....
Barley	3.60	6.15—6.40

BITUMINOUS

Bituminous not on market.

Pocohontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.00 a year ago.

*All-rail to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* are as follows:

ANTHRACITE

	Circular Current	Individual Current
Pea	$4.90	$5.65
Buckwheat	4.45@5.15	4.80@5.50
Barley	3.40@3.65	3.80@4.50
Rice	3.90@4.10	3.00@4.00
Boiler	3.65@3.90	....

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Gross	Mine Price Net	Gross
Central Pennsylvania..	$5.06	$3.05	$3.41
Maryland—			
Mine-run	4.84	2.85	3.19
Prepared	5.06	5.05	3.41
Screenings	4.50	2.55	2.85

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty, Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The ratte to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Current	One Yr. Ago	Current	One Yr. Ago
Pea	$3.45	$3.00	$4.35	$3.90
Barley	2.15	1.50	2.40	1.75
Buckwheat ..	3.15	2.50	3.75	3.40
Rice	2.65	2.00	3.65	3.00
Boiler	2.45	1.80	3.55	2.90

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes...	$2.65—2.80	$3.35—3.50
Mine-run	2.40—2.55	3.10—3.25
Screenings	2.15—2.30	2.85—3.00

Smokeless Coals	So. Ill., Pocohontas, Pennsylvania and W. Va.	Hocking, East Kentucky and West Va. Splint
Prepared sizes...	$2.60—2.85	$2.85—3.35
Mine-run	2.40—2.60	2.60—3.00
Screenings	2.10—2.55	2.35—2.75

St. Louis—Prices per net ton f.o.b. mines are as follows:

	Williamson and Franklin Counties	Mt. Olive & Staunton	Standard
6-in. lump	$2.65-3.00	$2.65-2.80	$2.30-2.40
2-in. lump	2.65-3.00	2.65-2.80	2.30-2.40
Steam egg....	2.65-2.80	2.35-2.50	2.30-2.40
Mine-run	2.45-2.60	2.45-2.60	2.00-2.15
No. 1 nut.....	2.65-3.00	2.65-2.80	2.65-2.80

RIVETS—The following quotations are allowed for fair-sized orders from warehouse:

	New York	Cleveland	Chicago
Steel 7/16 and smaller	30%	40%	40%*
Tinned	30%	40%	40%*

*For less than keg lots the discount is 35%.

Button heads, ¾, ⅞, 1 in. diameter by 2 in. to 5 in. sell as follows per 100 lb.:

New York..$6.09½ Cleveland..$5.35 Chicago..$5.50 Pittsburgh..$4.65

Coneheads, same sizes:

New York..$6.19½ Cleveland..$5.45 Chicago..$5.60 Pittsburgh..$4.75

REFRACTORIES—Following prices are f.o.b. works, Pittsburgh:

Chrome brick	net ton	$175.00
Chrome cement	net ton	75.00
Clay brick, 1st quality fireclay	per 1000	50.00– 55.00
Clay brick, 2nd quality	per 1000	35.00– 40.00
Magnesite, raw	ton	30 00– 35.00
Magnesite, calcined	ton	32.00– 35.00
Magnesite, dead burned	net ton	32.00– 35.00
Magnesite brick, 9 x 4½ x 2½ in	net ton	110.00–125.00
Silica brick	per 1000	50.00– 60.00

Standard size fire brick, 9 x 4½ x 2½ in. The second quality is $4 to $5 cheaper per 1000.

St. Louis—High grade, $55; St. Louis grade, $40.
Birmingham—Fire clay, $55-60; silica, $55-60.
Chicago—Second quality, $25 per ton.
Denver—Silica, $35 per 1000.

BABBITT METAL—Warehouse prices in cents per pound:

	New York		Cleveland		Chicago	
	Current	One Year Ago	Current	One Year Ago	Current	One Year Ago
Best grade	125.00	70.00	118.00	74.00	110.00	65.00
Commercial	70.00	40.00	23.00	22.00	22.00	25.00

SWEDISH (NORWAY) IRON—The average price per 100 lb., in ton lots, is:

	Current	One Year Ago
New York	$15.00	$13.00
Cleveland	15.00	12.00
Chicago	17.00	11.50

In coils an advance of 50c. usually is charged.
Note—Stock very scarce generally.

POLES—Prices on Western red cedar poles:

	New York	Chicago	St. Louis	Denver
6 in. by 30 ft	$5.59	$4.94	$4.94	$4.32
7 in. by 30 ft	7.40	6.60	6.60	5.80
7 in. by 35 ft	10.70	9.60	9.60	8.55
8 in. by 35 ft	12.20	10.90	10.90	9.65
7 in. by 40 ft	12.35	11.00	11.00	9.75
8 in. by 40 ft	13.75	12.15	12.15	10.65
8 in. by 45 ft	18.20	16.20	16.20	14.30
8 in. by 50 ft	21.85	19.45	19.45	17.15

10c. higher freight rates on account of double loads.

For plain pine poles, delivered New York, the price is as follows:

10-in. butts, 5-in. tops, length 20-30 ft	$ 9.00
12-in. butts, 6-in. tops, length 30-40 ft	11.50
12-in. butts, 6-in. tops, length 41-50 ft	12.50
14-in. butts, 6-in. tops, length 51-60 ft	21.00
14-in. butts, 6-in. tops, length 61-71 ft	23.50

PIPE—The following discounts are for carload lots f.o.b. Pittsburgh, basing card in effect July 2, 1917, for iron, and May 1 for steel:

BUTT WELD

Steel			Iron		
Inches	Black	Galvanized	Inches	Black	Galvanized

Malleable fittings, Class B and C, from New York stock sell at 5 and 5% from list prices. Cast iron, standard sizes, 34 and 5%.

BOILER TUBES—The following are the prices for carload lots f.o.b. Pittsburgh, announced Nov. 13, as agreed upon by manufacturers and the Government:

Lap Welded Steel		Charcoal Iron	
3½ to 4½ in.	34	3½ to 4½ in.	12½
2½ to 3¼ in.	24	3 to 3¼ in.	+ 5
2¼ in.	17½	2½ to 2¾ in.	+ 7½
1¾ to 2 in.	13	2 to 2¼ in.	+22½
		1¾ to 1⅞ in.	+35

Standard Commercial Seamless—Cold drawn or hot rolled:

	Per Net Ton		Per Net Ton
1 in.	$340	1¾ in.	$220
1¼ in.	280	2 to 2½ in.	190
1⅜ in.	270	2¾ to 3¾ in.	180
1½ in.	220	4 in.	200
		4½ to 5 in.	220

These prices do not apply to special specifications for locomotive tubes nor to special specifications for tubes for the Navy Department, which will be subject to special negotiation.

POWER

Vol. 47 NEW YORK, JUNE 11, 1918 No. 24

Success—On Things in General, Personal and Otherwise

"I would like to study, but haven't the time." This is a familiar complaint. But consider the man who always has some educational literature with him, reading at spare moments, waiting for his dinner order, on train, trolley or ferry, homeward bound. Many possible moments exist for all of us; like the pennies, in the end they count and should be saved. One's time has a cash value.

Do you ridicule the man who studies up, saying "Work can be learned only by contact"? When he attains that position which you had thought to be yours simply by virtue of long service, do you complain and berate your luck? The man too valuable to longer occupy the lower position is given the one ahead; though not working at it, still he had acquired by study the fundamentals of the undertaking. He who does not progress surely goes backward.

Think not of the pleasures others have during social hours while yours is only study. Endurance wins. In games of skill a fair degree of proficiency is to be admired; beyond that, it is a waste of time, and no one cares to play with a professional.

Do not let personalities interfere with your progress. But some other fellow may. Study your own to avoid friction; no one advances on merit alone. Personality and temper control are gained by the preservation of health. One should not study to the detriment of health, but maintain that course compatible with progress which conserves the health necessary to enjoy the fruits of labor.

Money is not always a measure of success. Reasons of existence give each his part in the world's undertakings. Though you only have a ditch to dig and dig it well, success is yours; dig it better and a goal is defined for the other man. Branch out with success and extend it to all things, even to your leisure moments.

Is it impossible to advance? Are there necessary restrictions or limitations beyond which you may not go? This is your individual problem. Nothing is perfect; never complain; strive to make right, that is the purpose of your existence. Work cheerfully or choose an environment suited to your temperament; someone specially fitted may win in the place you vacate.

A fair appearance consistent with your position is commendable. Harmony, with utility in design, sells goods, so your good appearance impresses others, commanding respect and results.

You save for your employer a small amount and lift your head with pride, little realizing that your salary is his investment—you the instrument of service to economize for him. Equal results could be obtained by others; your salary should be the small percentage of your economies, otherwise you have lost where there is no reasonable return upon the investment.

Command the attention of those above, but not in a spectacular manner, advertising your ability in a modest way. Work well, even if not appreciated; others are watching, and even those in minor positions may at some future time recommend or employ.

Contributed by T. W. Reynolds

Soot and Soot Blowers

Nature of soot and its effect on heat transfer through boiler heating surface. Relative steam consumption of mechanically operated soot blowers versus hand cleaning. Effect on the coal pile, labor required and maintenance cost of mechanical blower as given by a number of users.

DURING recent years the boiler room has gradually emerged from a position of secondary importance to a primary element in the cost of power generation. Boilers have been growing in size, combustion rates have increased, and greater loads per unit of steam-making surface are being carried. With the operating conditions becoming more severe and fuel cost high above the normal level of years past, closer scrutiny is being given all factors affecting economy.

Of all the preventable losses, that caused by the formation of soot on the fire surfaces of the boiler is perhaps the most troublesome. Cracks in the setting may be detected, and the leakage of air into the setting may be stopped. Proper insulation will reduce radiation, and scale on the water surfaces may be eliminated to a large extent by the use of pure or softened water. The formation of soot and ash, however, is universal and continuous as long as there is an active fire under the boiler. Depending upon the degree of combustion and arrangement of the setting, the quantity of soot varies and its character differs with the fuel, but there is no stopping of its formation. Even if conditions were ideal and combustion complete, a heat-insulating coating composed largely of ash would form on the tube surface.

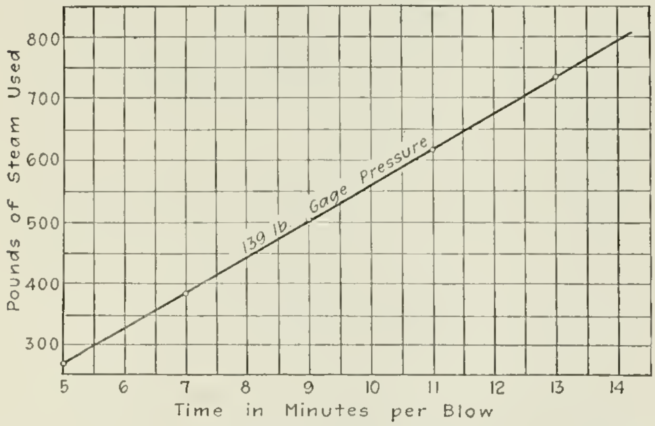

FIG. 1. TOTAL STEAM REQUIRED FOR PERIODS BLOWER IS IN OPERATION

As a rule the soot found in boilers is not pure soot or carbon. It contains a varying proportion of ash, so that the color may be light gray, red, brown or, where conditions are particularly unfavorable to good combustion, black. In coming from the furnace, the soot particles are more or less plastic and readily adhere to the metal surface of the tubes. Unless the deposit is quickly removed, the carbon on the tubes near the fire will burn out in part, fusing the various ingredients into a hard coating, which increases rapidly as the gas temperature rises due to the insulation of the tubes. In water-tube boilers it is not uncommon to find on the heating surface near the fire hard clinker-like formation in some cases bridging the tubes. Even with efficient and frequent cleaning it is practically impossible to keep the lower tubes near the fire entirely free of this slag-like formation. Farther back the soot does not contain so large a percentage of ash. It is usually darker in color, and the formation is not cemented together. Loose deposits rest on all retaining surfaces, such as the upper portions of the tubes.

With all kinds of fuel then there is formation of soot. Anthracite contains a low percentage of volatile matter, but may run high in ash, so that the deposit is largely the latter constituent and is usually of a light powdery character. With bituminous coal, high in both volatile and ash, there is a large percentage of carbon in the soot, particularly if the furnace conditions are not favorable to good combustion. In waste-heat boilers deposits of fine powdered dust carried along with the gas are to be found, and even with oil fuel there is some formation of soot. Due to excellent combustion the quantity is small, but as the deposit is pure soot of high insulating value, its removal is important from an efficiency standpoint. The soot evil also extends to the economizer, the deposits resembling the boiler soots. Due to the lower temperatures the formation is more profuse and its interference with heat transmission relatively greater as the difference in temperature between gas and water is less.

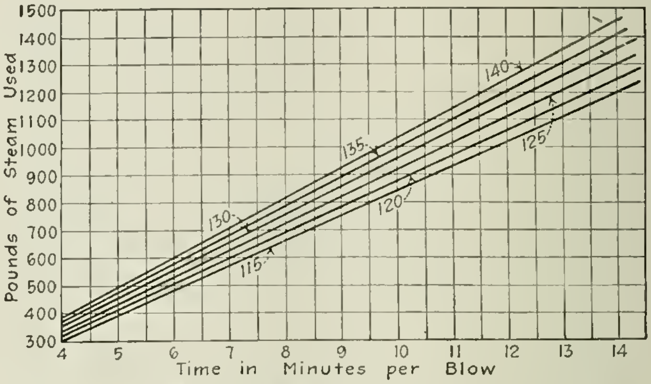

FIG. 2. STEAM CONSUMPTION OF 2-IN. BLOWER FOR VARIOUS PRESSURES

It has been commonly stated that next to loose wool, loose lampblack or soot is the best insulator known. In this capacity it is ahead of hair felt, and is more than five times as effective as fine asbestos. All this may be true, but boiler soot is not all lampblack. The varying percentages of ash and the density and structure of the deposit will naturally affect the insulating properties. Besides, the coating is not evenly distributed so that part of the surface at least will be comparatively clean. If the maximum heat transfer through the boiler tubes is to be maintained, however, all the heating surface must be kept clean, and this is particularly true where boilers are forced over normal rating, as is the practice in modern plants. If the soot is allowed to remain, another bad feature is the formation of carbonic and sulphuric acids, which act on the metal of the boiler, causing leaky tubes and general deterioration that will shorten the useful life of the boiler. It is quite evident, then, that soot must be removed if the best results are to be obtained, and the question at issue is the easiest and most efficient method of doing it.

For the purpose there are the hand lance and the mechanical blower. The former, consisting of a rubber hose and nozzle, was the first device to be used. It is of course simple and the initial cost is small. Two men are required to operate it: one at the boiler to handle the nozzle and the other at the steam valve. The work is naturally hot, dirty and disagreeable and on a medium-sized boiler takes from twenty to thirty minutes. Usually there is not more than one and at most two blowings per day of twenty-four hours. The lance is inserted through dusting doors in the setting, and there is no opportunity for the operator to see the result of his work. Unless he is conscientious beyond the average, the surface may be poorly cleaned and some sections are neglected entirely. Usually, the lance does not reach all the heating surface, the area covered being determined by the kind of dusting doors, the width of alley space at the side of the boiler and the range of the lance due to the angle of the dusting door. Another objection commonly advanced against hand-blowing is the fact that when soot is blown across the tops of the tubes it strikes the battery wall and tends to pile up on the far tubes, contrary to the argument that the draft will carry it off.

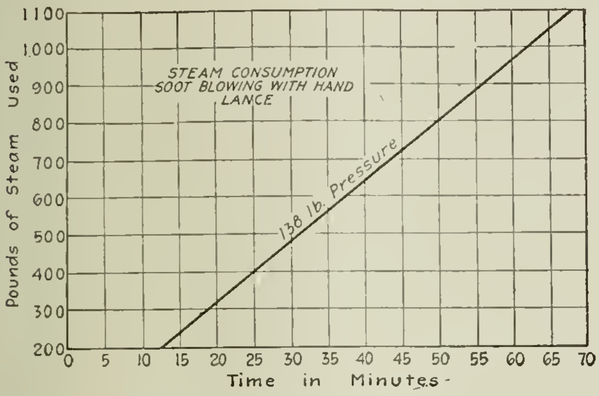

FIG. 3. STEAM CONSUMPTION WITH HAND LANCE

There is the additional objection of large quantities of cold air being drawn into the setting during the period the steam lance is in operation. This means less efficient combustion. As expressed by A. W. Conklin, in *Power*, July 13, 1915, the time required to clean a boiler with a steam or air lance is about three times that necessary with a mechanical blower, and the results obtained are about one-third as good. In a series of comparative tests in soot blowing, it was found that the amount of steam required for one operation of the mechanical blower was about the same as that used in blowing the boiler by hand. In other words, the amount of steam used by the blower in 6 minutes, the time required to clean the boiler, was nearly the same as that used by the steam lance in 25 minutes for the same operation. The mechanical blower, however, showed a saving of 5 per cent. over hand-blowing, because the heating surfaces were more thoroughly cleaned. This figure appears to be conservative and when in average practice neglect or less frequent cleaning are factors, the saving may easily be more.

Continuing with the results obtained by Mr. Conklin, Fig. 1 shows the steam consumption of a soot blower equipped with 1½-in. piping to the blowing elements. The steam pressure was 139 lb. gage and the superheat about 20 deg. Between the main steam header and the nozzle plugs there was a drop of about 10 lb. pressure when the blower was in operation. The test was made on a 300-hp. water-tube boiler vertically baffled for three passes. Two blowing elements in each pass cleaned the tubes. In addition an element served the superheater and another was placed in the rear combustion chamber. Fig. 2 shows the steam consumption of a 2-in. blower at different steam pressures and 20 deg. superheat on a 500-hp. boiler of the same type served by the same number of blowing elements. Fig. 3 gives the steam consumption of a hand lance on the smaller boiler. With the latter the superheater tubes were not blown, nor was the rear combustion chamber cleaned, but the steam consumption was about the same as that required for one blow with the mechanical blower. The blower required 29 min. and the steam at 138 lb. pressure was used 25 min. at the rate of 16 lb. per min. Temperature readings taken at the top row of tubes, third pass, showed that the gases from the mechanically cleaned boilers were anywhere from 80 to 100 deg. lower, say 520 deg., as compared to 620 deg. for the hand-cleaned boiler. This corresponds to a saving of from 4 to 5 per cent. made possible by more efficient and more frequent cleaning.

Drop in Uptake Temperature

From general observations and figures from various tests a general rule has been figured out that for every 20 deg. drop in the uptake temperature due to the removal of soot from the heating surface, there is a saving of approximately 1 per cent. in fuel. It is well to bear in mind that a drop in flue-gas temperature may mean better absorption of heat or it may mean a temporary cooling of the surface by the blowing steam. The time element in the return of the temperature to that before blowing is the deciding factor. A rapid recovery indicates cooling while a slow gradual rise in the temperature shows efficient cleaning. Fig. 4 is an example of the latter condition. The curve is a plot of flue tem-

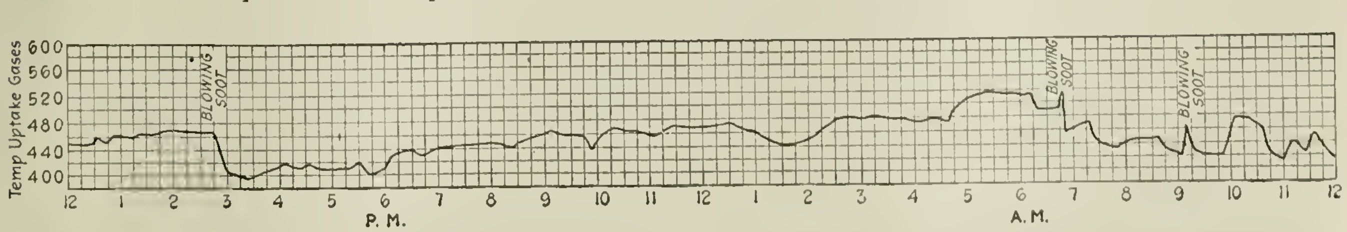

FIG. 4. EFFECT OF SOOT BLOWING ON FLUE TEMPERATURE IN A HORIZONTAL VERTICALLY BAFFLED BOILER

peratures in a horizontal vertically baffled water-tube boiler burning Illinois coal in an underfeed stoker. After the blowing at 2:45 p.m. there is a sudden drop in temperature of 70 deg. The succeeding rise in temperature is gradual, as the curve does not reach the original level until midnight, about nine hours later.

Labor is another item entering into the comparison. The mechanical blower required but one man and the time of blowing is, say, one-fourth as long, so that the ratio in this case was 8 to 1, and with very large boilers it may be considerably higher. Local conditions, size of plant, etc., determine whether the saving in time will be sufficient to dispense with the services of employees retained for this work.

Objections offered to the mechanical blower are initial cost, running from 5 to 10 per cent. of the cost of the boiler, the burning out of the elements exposed to the hottest gases direct from the furnace, and warping. The objection last named, warping, has always been a serious problem. It is a well-known fact that metal begins to warp long before it reaches a temperature that will cause corrosion or burning of the metal. For that reason it is necessary to construct the element so that it will have strength to resist the warping, for as soon as this action begins, the element will be thrown out of line, it will bind in the bearings and the operator will be unable to turn it.

INITIAL COST SMALL

The initial cost is comparatively small when compared to a 5 per cent. saving in the fuel bill, the reduction in labor and the convenience of operation. Destruction of the elements near the fire has been obviated to some extent by the use of special metal having high heat-resisting qualities, and by so placing the elements that they are protected from the direct heat of the furnace when in the nonoperating position. Corrosion, due to back suction of the boiler gases into the blowing elements, has been reduced by the use of special air valves, and special precautions have been taken to drain the piping system of the blower to prevent condensation being forced out onto the heating surface to interfere with soot removal and to corrode the metal. These various improvements, better placing of the elements and nozzles of improved design have so perfected the mechanical blower that, according to reports from numerous users, the services rendered are excellent and the maintenance charges are comparatively small.

While users of the mechanical soot blowers realize that they are getting better heat transfer, that the flue gases are lower in temperature and that the boiler efficiency has been improved, there is a lamentable lack of specific data showing the saving actually effected and the average cost of maintenance. The blowers have been installed. They are giving satisfaction. The boilers will carry more load, and it is known that the flue temperatures are considerably lower than previous to the installation. During the first two or three years of use repair parts are required occasionally. Depending upon the service the average life of the blower is at least five or six years. The labor of blowing has been reduced, and as the work is less arduous, it is performed more frequently and with better results.

Such was the gist of replies from a large number of power-plant owners and engineers to whom inquiries had been sent by the writer concerning the saving in fuel and labor effected by the installation of mechanical blowers, the cost of maintenance and the degree of satisfaction the blowers gave in service. The substance of some of the replies, more specific than others, are presented in the following:

The Iowa Falls Electric Co. had equipped three Edge Moor water-tube boilers of the four-pass type with soot blowers. Two of the boilers were rated at 410 hp. and the other at 550. The boilers had previously been blown by hand, and the work required the full time of one man at a cost of $850 per year. In their opinion it took a remarkably good man to stand up beside a hot boiler and blow every tube. Frequently some of the tubes were missed, and the result was a reduction in efficiency. Besides, a man could not hold a hose carrying 175-lb. steam pressure. It had taken the company two months to get all the old scale off the tubes, caused by blowing them with wet, low-pressure steam. The principal advantages of the mechanical blower in their estimation was the fact that full boiler pressure could be used and that better results were obtained. Since the installation of the blowers the services of the man previously mentioned had been dispensed with, and the firemen were blowing the tubes twice on every shift. The saving in coal was placed at 15 per cent. The blowers had been in service one year, and the maintenance expense had been the cost of one pint of oil to lubricate the swing joints.

MAKE A SAVING

The Iowa Railway and Light Co., of Cedar Rapids, had installed mechanical soot blowers on 29 Edge Moor water-tube boilers during a period extending from 1909 to 1918. The company knew that the blowers were a great help both in labor and economy, but could give no definite figures. It had been found that the blowers would not keep clinkers off the first row of tubes. There was a chance for improvement here.

In the plant of the Indianapolis Light and Heat Co. 14 boilers, ranging in size from 500 to 800 hp., were equipped with mechanical blowers. If properly operated, the blowers saved approximately 15 per cent. in fuel and labor. About 12½ per cent. of this saving was attributed to higher boiler efficiency and 2½ per cent. to a reduction in labor cost. The maintenance had been approximately $5 per installation per month.

The Richmond Light and Railroad Co. had blowers on ten 606-hp. B. & W. boilers equipped with stokers. The maintenance on the blowers, which had been installed from one to two years, had been practically nothing. The company had no accurate data to show the saving in coal and labor, but was satisfied that the blowers were a good investment.

The Edison Electric Illuminating Co. of Brooklyn had in use blowers on 17 B. & W. boilers averaging 650 hp., and 45 additional units were being installed. Installation work had begun in November, 1916, and no definite figures as to fuel saving were available, as the majority of the boilers were still blown by hand. In the opinion of the operating engineer there was no question that the boilers were much cleaner by the use of the mechanical soot blowers, and that a saving in fuel must result. When all the soot blowers were installed, the labor saving would eliminate the services of five men and would amount to about $13 per day.

Soot blowers on 4900 hp. of Stirling boilers are in use at the plant of the Indiana Railways and Light Co., of Kokomo, Ind. No tests had been made to determine the percentage of saving. Cleaner tubes so clearly indicated a saving that the question had not been analyzed. It had been their experience that the soot blower complete had to be removed in from five to six years.

Four 750-hp. Bigelow-Hornsby boilers in the plant of the Salem Electric Lighting Co., of Salem, Mass., had been equipped with soot blowers in 1915; five blowers were installed on 280-hp. Heine boilers in the plant of the Rockland Light and Power Co., of Nyack, N. Y., in 1914, and in the same year a 600-hp. B. & W. boiler of the Malden Electric Co., of Malden, Mass., was equipped with a blower. In the plant first mentioned the saving in labor was $675 per year; in the second plant $411 per year, and in the Malden plant the labor saving was undetermined. Blower repairs in the three plants had been negligible. In the opinion of the engineering manager controlling the three properties, there was no question but that there had been a saving in fuel on all the boilers equipped with mechanical soot blowers, as it was possible to clean the tubes twice in twenty-four hours so that the heating surface was maintained in much better condition. No exact data were available.

BETTER THAN AIR BLOWERS

The Central Hudson Gas and Electric Co., of Poughkeepsie, N. Y., had equipped six of eight Stirling boilers with mechanical blowers. These blowers were much more effective than the compressed air they had previously used, and there was a considerable reduction in labor.

Installation of soot blowers on two 400-hp. Heine water-tube boilers in the plant of the Chester Valley Electric Co., of Coatesville, Penn., in the year 1911, had resulted in a saving in the operation of the plant roughly estimated at 5 per cent. This figure was considered conservative and was divided into 1 per cent. in labor and 4 per cent. in fuel. The maintenance charges, which had been small, were placed at $100 in seven years.

With blower installations on two 350-hp. Heine boilers and two Stirling boilers for several years, the Texas Power and Light Co. placed the cost of upkeep at $5 per blower per year, and over hand-blowing estimated a saving in fuel of approximately 10 per cent.

The public lighting plant of the City of Detroit had installed soot blowers on two 685-hp. Stirling boilers Apr. 21, 1916. To clean the soot from two 400-hp. Stirling boilers by means of a steam hose from ladders required the labor of two men for about three hours. With the mechanical blowers the battery of two 685-hp. boilers was cleaned by one man in one-half hour, the ratio being 12 to 1 in favor of the mechanical blower. So far there has been no expense for maintenance.

One of the large central station companies of the country has equipped 55 boilers with mechanical soot blowers. These are of competitive types, and a few of home manufacture. Fifteen of the installations have been made on Stirling boilers rated at 2365 hp. that operate between bank and about 200 per cent. of rating. On overload the temperatures are high and the conditions severe, so that it has been found necessary to assist in the further development of the blowers. To clean one of the large boilers by hand requires twelve to fourteen hours' time with two men operating. These men receive 38 cents per hour, so that the labor cost for hand-blowing averages about twenty-six hours of 38-cent time, or just under $10 per 2500 boiler horsepower per twenty-four hours.

With soot blowers installed two men blow a boiler in about one hour. They blow each boiler three times a day so that the total labor cost approximates $2.30 per 2500 boiler horsepower per twenty-four hours. Thus the labor item is reduced to less than one-fourth, and the boiler has the advantage of three cleanings a day. The job is much better done, and no useless air is admitted through open doors. The effect of this factor will be appreciated when it is noticed that it takes from twelve to fourteen hours to blow one of the boilers by hand.

To clean one of the big boilers with a mechanical blower required about 3500 lb. of steam per blow. Three operations per day would require about 10,500 lb. of steam per 2500 boiler horsepower every twenty-four hours.

The maintenance charges on soot blowers had not been separated from certain other somewhat similar costs, but it was estimated that soot blowers properly installed could be kept in good operating condition with a maintenance expenditure of not over $200 per 2500 boiler horsepower per year. The average charge had been higher than this, but it was due to the fact that certain parts as originally designed and installed had given out frequently and had to be replaced. Because of imperfect methods used for measuring flue-gas temperatures, accurate data were not available to indicate the thermal advantage obtained from the use of soot blowers. It was believed safe to assume, however, that mechanical soot blowing maintained a flue-gas temperature about 30 to 40 deg. lower than could be maintained with hand-blowing, and unless the latter operation was completely and conscientiously done, the difference would be more nearly of the order of 80 to 100 deg. less.

Loss of Flowage Rights

Under the laws of New York, right to dam a stream, when acquired and held under an express deed or grant, cannot be lost by mere nonuse unless the disuse has continued for at least twenty years. And when a dam has been maintained at a given height for that period or longer, a prescriptive right is acquired, irrespective of any express grant. Where there has been no relinquishment of an acquired right to flood lands, through express relinquishment or continued nonuse for twenty years, the owner of the dam is entitled to reconstruct it at such height as to overflow upper lands to the full extent permitted under the original grant of right. Hence, the fact that an old dam may have leaked for many years, less than twenty, will not affect the right of the owner to repair the leaks, or reconstruct the dam, so long as no more land is overflowed than was overflowed in the original enjoyment of the right. (New York Supreme Court, Ulster County; Geiger vs. Divine, 167 New York Supplement, 263.)

Augustine Rotary Two-Cycle Super-Induction Gas Engine

ONE of the most widely used engines for airplane work is the revolving air-cooled motor, of which there are several designs, operating on the four-stroke cycle. The distinguishing feature of this type of engine is that the crankshaft and cranks are stationary and the cylinders revolve about this shaft. This produces the same relative motion of the piston to the cylinder as if the cylinder were stationary and the crank revolved, as in the case of an ordinary reciprocating engine. These engines are generally made with 5, 7, 9 or 14 cylinders and range from about 50 to 100 hp. each.

A new design of rotary gas motor is the Augustine rotary two-cycle super-induction air-cooled engine, Fig. 1, which has been developed by the Augustine Automatic Rotary Engine Co., 1862 Elmwood Ave., Buffalo, N. Y.

Figs. 2 and 3 illustrate the general design of this engine; the former is a sectional view through the motor in a plane at right angles to the axis of the driving shaft and centrally through the cylinders, also showing the relative positions of the pistons in the radial cylinders and the stationary shaft, bearings and connecting-rods. Fig. 3 is a sectional view in the plane of the axis of both the stationary and driving shafts, showing the assembled parts and how the lubricating oil is carried in copper tubes to the bearings and how the oil is kept cold by the incoming charge of gas.

The fuel gas is drawn from the carburetor through the hollow shaft *A*, Fig. 3, by the pumping action of the piston and is delivered to the crank casing, where it is put under slight compression, the degree of compression being controlled by the throttled condition of the carburetor. The passage of the fuel gas is from the hollow shaft *A* through the stationary controlling valve *B* and intake pipe *C* to the space *D* in the cylinder between the piston and the cylinder head, as shown by the arrows. As the sleeve valve *E* has closed the exhaust ports when the piston is at the compression position, the gas in the space *D* is forced back through the pipes *C* and *F*, past the valve *B* and into the crank casing of the engine when the piston begins its outward stroke, the valve *B* having moved to permit of its passage and so has cut off the supply of gas from the carburetor from the cylinder that has reached the compression stroke.

Fig. 4 is a sectional view of the stationary controlling disk valve showing the alternately intaking and discharging pipes that lead to the different cylinders. It also shows by the arrows the intaking of the charge from the carburetor and the discharging of the gas charge into the inner chamber by positive cutoffs above and below, the engine rotating in the direction of the curved arrow. As shown, the gas passes to the chamber *D*, Fig. 3, at the same time and is being forced into the crank casing from two opposite cylinders during the same period.

The fuel gas passes directly from the crank casing to the cylinders, entering through the intake ports *G*, Fig. 3, which are at the inner ends of the cylinders. A separate view of the piston, ports and cylinder is shown in Fig. 5, which also shows how the super-induction is effected, the sleeve *E*, Figs. 3 and 5, having closed the exhaust ports and the full pressure of the inner chamber being admitted into the cylinder before cutoff and compression begin.

With the piston at the inner end of the cylinder, Fig. 6, and the exhaust ports closed, the cylinder is filled with fuel gas drawn from the carburetor through the hollow shaft and intake pipe leading to the outer end of the cylinder. The greater piston area on the pump side is responsible for the super-charge that is brought in and then transferred to the inner chamber as the piston reaches the other end of the stroke. Compression is effected between the inner face of the piston and the inner end of the cylinder before exploding and expanding, and the spark plug *H* is located in the center of the charge. The screen on the intake ports *I* is to prevent backfiring.

After the explosion in any one of the six cylinders takes place, the burnt gases are expelled through the exhaust ports *J*, Fig. 3, at the outer end of the cylinders. These exhaust ports are controlled by a sleeve which is positively moved by the cams and push-rods *K* and *L*, the movement of the sleeve being so timed as to close the exhaust ports prior to the closing of the intake ports *G*. By this super-induction, brought about through the closing of the exhaust ports and the pumping capacity of the piston, which can deliver a large volume of gas to the cylinders, a very high volumetric efficiency is obtained, even at high altitudes in airplane service where low atmospheric pressures are encountered.

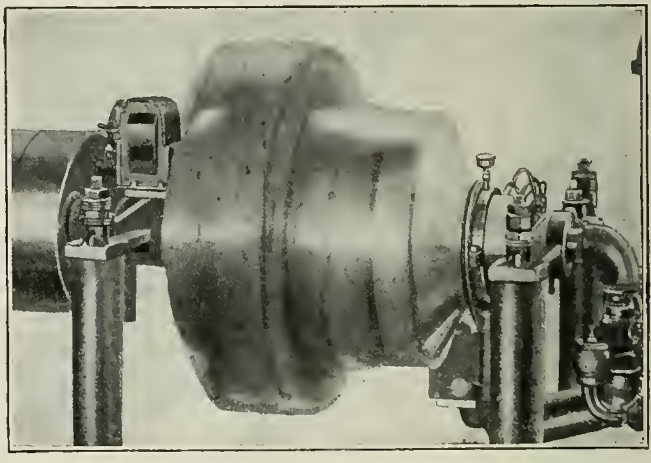

FIG. I. THE AUGUSTINE ROTARY ENGINE RUNNING AT HIGH SPEED

An idea of the action of the gases in each cylinder may be obtained from an examination of Figs. 7 and 8. The former shows the piston position just as the exhaust gases are released by the piston uncovering the ports and thereby relieving any pressure before the inlet ports are open. Fig. 8 is a similar view, showing the intake ports open and the cylinder fully scavenged of the burnt gases and the sleeve at the point of closing the exhaust ports. It also illustrates how the spark plugs *H* have a complete scavenge with the new, clean charge of dry gas, insuring easy ignition. As the exhaust ports are at the outer end of the cylinder and the inlet ports at the inner end of the piston cylinder, this prevents cycloning of the inrushing gases and causes natural scavenging, owing to a "uniflow" of the gases.

In Fig. 9 is shown a partial view through the upper portion of a cylinder at one side, with the piston just closing the exhaust ports and the sleeve for the closing of the exhaust ports about to move and uncover them. At this position of the piston there is no pressure on the sleeve, therefore it is moved practically without friction. Fig. 10 is a similar view showing the exhaust ports uncovered by the sleeve and the piston just reaching the ports, which it also uncovers and thereby effects the exhaust. After the compressed charge has been exploded and the piston has moved to its outer stroke, the sleeve valve *E*, Figs. 3, 9 and 10, uncovers the ports *J* and the incoming charge of fresh gas from the crank casing forces the burnt gases out through the ports *J* into the exhaust pipes *U*, Figs. 2 and 3. This cycle of events takes place in each cylinder in rotation.

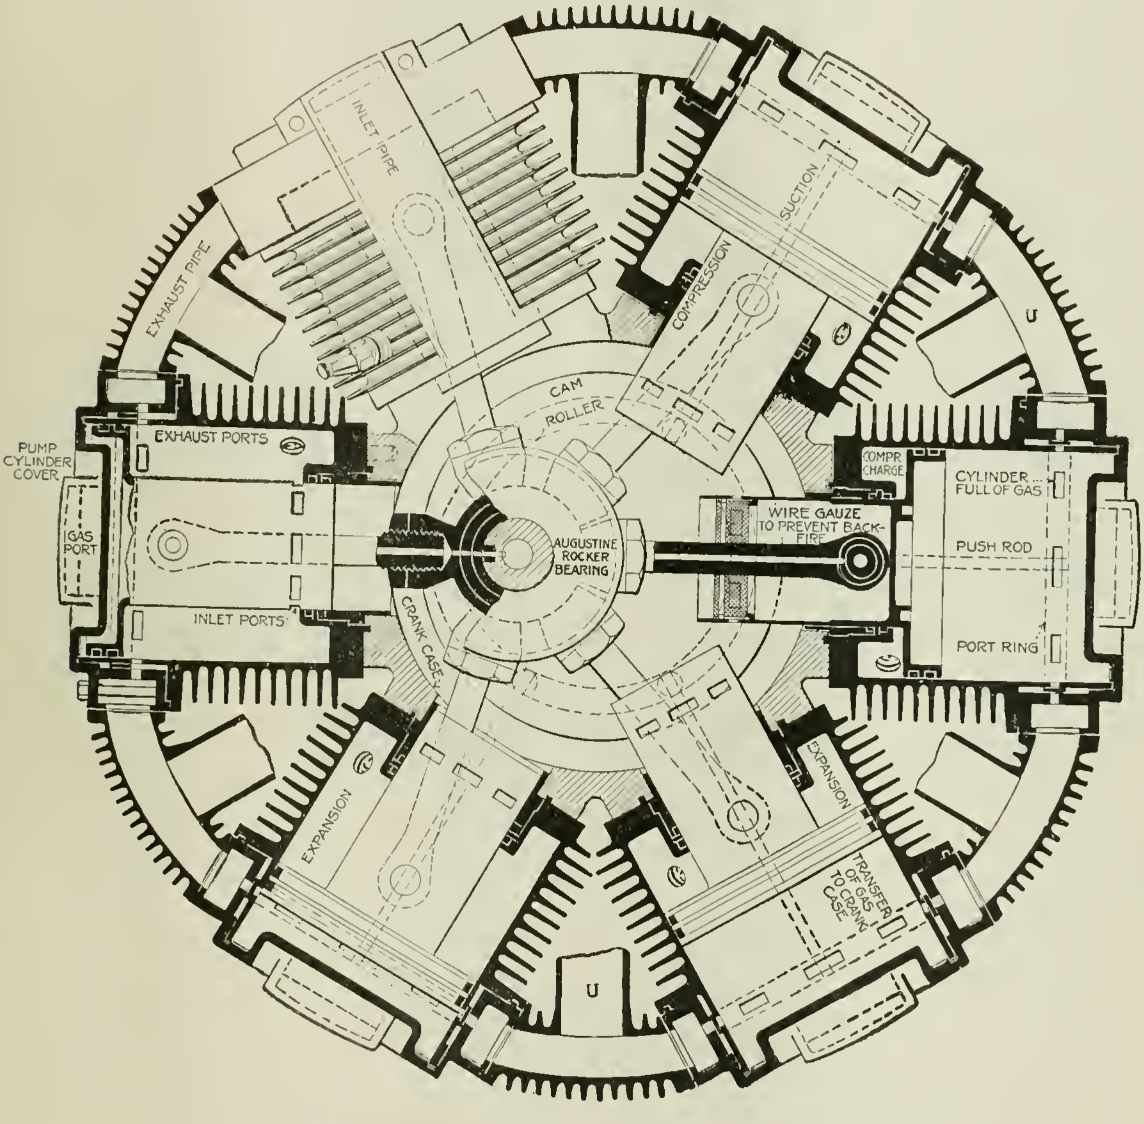

FIG. 2. END SECTIONAL VIEW THROUGH THE AUGUSTINE ENGINE

In the operation of the rotary type of engine centrifugal force has to be contended with, and this becomes an enormous factor in a high-speed engine. The Augustine engine overcomes this difficulty by arranging the expansion and compression chambers for the fuel gases so that the expanding gases work against the inner space of the piston, forcing it outward and pulling on the fixed crank to turn the engine rather than thrusting against the crank. The expanding force of the gas against the piston operates in the same direction as the centrifugal force and is added thereto, and does not destroy the balance of one piston against the other. In this connection another advantage is accomplished in that the thrust of the expanding gases against the cylinder forces the cylinder against the crank casing, so that the only necessary connection between the cylinder and the crank casing is to overcome the centrifugal action on the cylinder. Records show that many accidents have occurred by the cylinder breaking loose through the tremendous pressure of the expanding gases combined with centrifugal effect, which tends to force the cylinder outward. In this engine, however, this is overcome because the pressure of the expanding gases against the inner end of the cylinder tends to hold it seated against the crank casing.

An essential feature in an airplane engine is extremely light weight. In this engine each cylinder is divided by the piston into a pumping chamber and an expansion and compression chamber for the fuel gases, as already mentioned. The gases are pumped by the same piston that is acted upon by the expanding gases, thus making the piston double-acting. By using the one cylinder both for pumping gases and for the expansion of the gases in turning the engine, the latter may be made very light, because the expansion of the gases is against the inner end of the cylinder and the crank casing, and the outer end of the cylinder is only subjected to the suction and the discharge of the gases. In other words, the force of the expanding gases is practically taken up by the piston head and the crank casing itself. As the sleeve that controls the gas ports is also timed to cover the exhaust ports when the outer end of the cylinder operates as a pumping chamber, this not only obviates the loss of fuel gases being pumped, but also prevents the burnt gases from being thrown back into the pumping chamber.

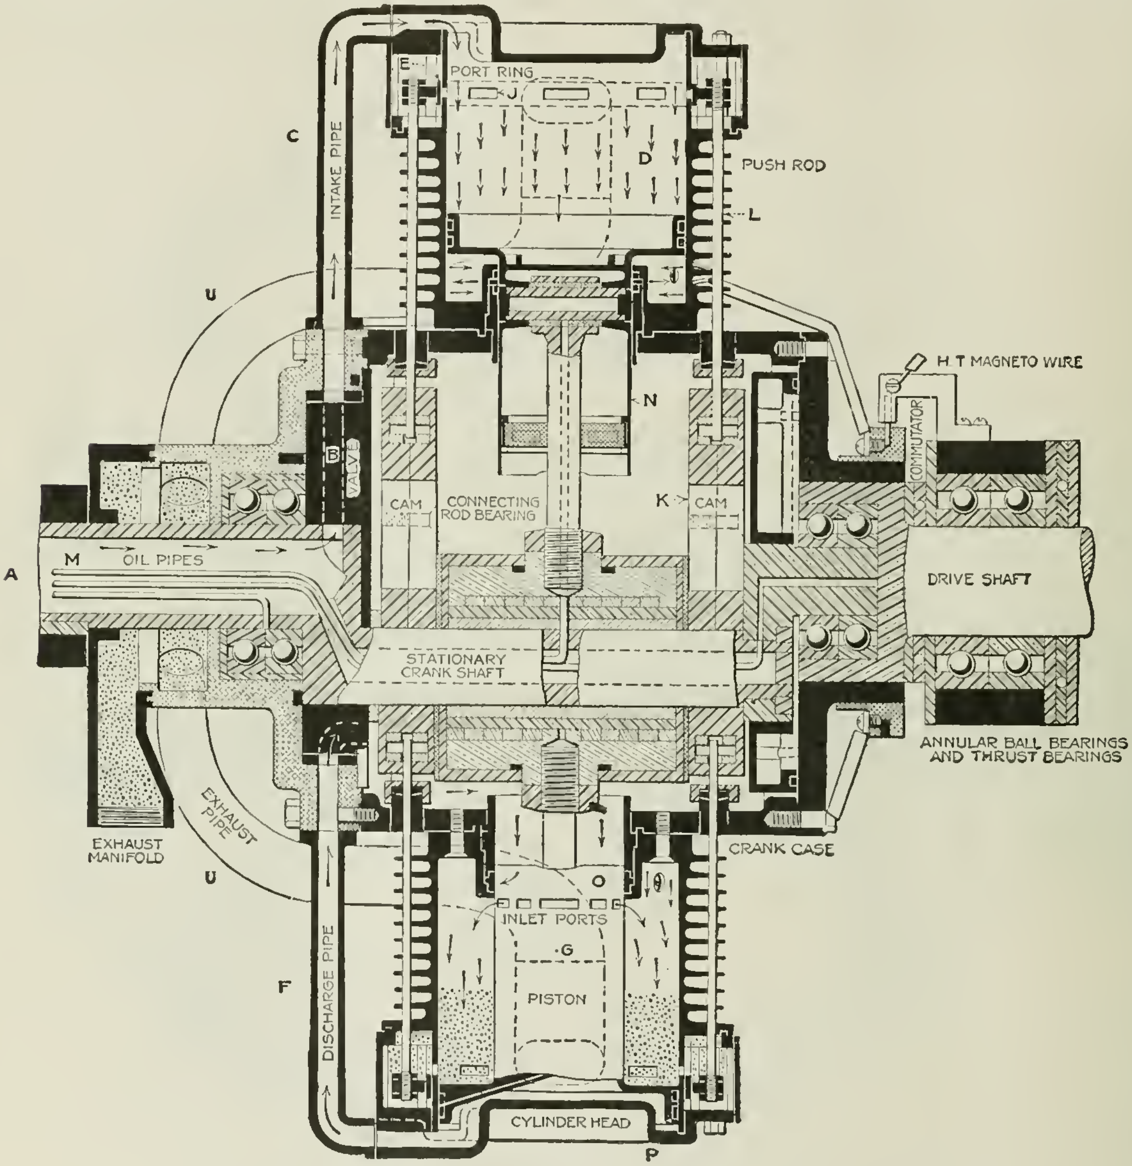

FIG. 3. SIDE SECTIONAL VIEW THROUGH THE TWO-CYCLE ROTARY ENGINE

The cylindrical projection *N*, Fig. 3, extends inwardly from the piston head and from the housing from the piston-rod connection and also contains the intake port. This cylindrical projection is opened to the crank casing so that the cooled fuel gases pass up into them and the moist gases, particularly, are carried by centrifugal force into the cylindrical projection, which becomes in a way a vaporizer for gasifying the fuel. As the intake ports are at the extreme inner end of the cylindrical portion carried by the piston, the moist gases are carried by the centrifugal force past the intake ports and gasified, and only dried gas passes through the intake ports to the cylinder. Furthermore, the fuel gases come in contact with the inner central portion of the piston head, and at the same time the fuel gases in the pumping chamber come in contact with the outer face of the piston head. This tends to keep the piston head cool while the heat units tending to accumulate therein are utilized for gasifying the fuel.

The piston with its cylindrical projection has a two-point bearing, one at each end of the expansion chamber. As the piston travels, the connecting-rod assumes a position at an angle to the longitudinal center line of the cylinder, and this has caused considerable difficulty in previous engines, owing to the side thrust or twist of the piston wearing the cylinder wall. By this construction, however, where the piston has a two-point bearing, as at *O* and *P*, Fig. 3, this side thrust or lateral twist in the piston is taken care of with little or no wear of the piston on the cylinder wall. Furthermore, by this two-point bearing the extent of the contact surface between the piston and the cylinder wall is reduced to a minimum and the friction incident to the travel of the piston is thereby reduced.

The exhaust ports are large and are disposed about the end of the cylinder. The intake ports are disposed about the cylindrical portion carried by the piston and are in line with the exhaust ports. As a result, when the exhaust ports are open and the intake ports uncovered, the gases rush through the latter and force the burnt gases out of the former, thus scavenging the cylinder. As already stated, the central portion projecting from the piston prevents cycloning of the inrushing gases and intermixing with the burnt gases.

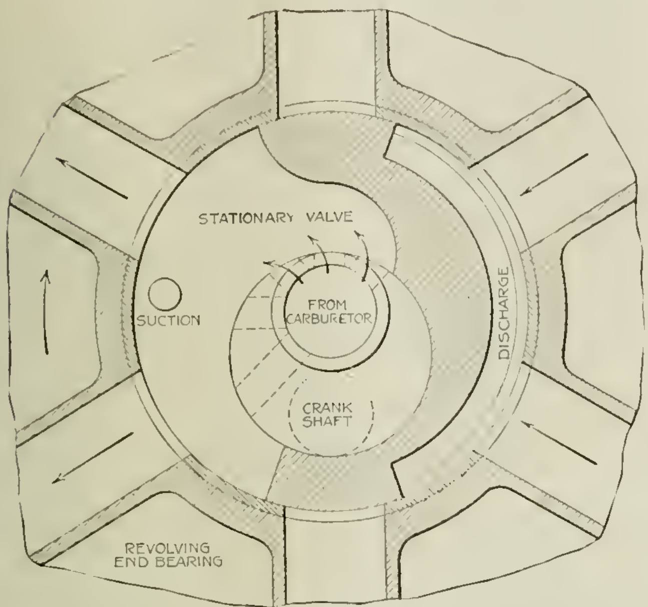

FIG. 4. SECTION THROUGH THE STATIONARY CONTROLLING DISK VALVE

Each piston rod is connected to a pair of rings, and these rings are nested and engage two floating sleeves mounted on a fixed crank. By having a pair of rings, all side thrust on the piston rod is avoided. The end cups surround the ends of the connecting bars carrying the rings. A compression ring is slipped over the connecting bars and engages the groove therein. This compression ring also engages the inner surface of the cups and thereby forms in each cup a lubricating pocket. The oil for lubricating the crank is carried by a copper tube through the hollow fixed shaft as at *M*, Fig. 3, and passes out through oil grooves in and about the floating sleeve into the end cups and also out through the connecting-rod to the wristpin and to oil ducts leading to the cylinder walls. This arrangement gives lubrication for every desired part of the engine, and also insures that the fuel gases are free from the lubricating oil.

A side elevation through the center of the self-aligning bearing is given in Fig. 11, in which the two inner sleeves and the oil channels are shown, also the end cap bearings that inclose the outer section of the bearing. The two expansion rings on the inner ends of the caps are for retaining the oil film. Fig. 12 is an end view showing the various sections of the self-aligning bearing and the oil ducts leading up through the connecting-rods to the wristpin, through which the oil is equally distributed by centrifugal force through all parts while the engine is in operation. The ensemble of this self-aligning bearing insures alignment of the piston rods between the crank and the wristpin centers and at the same time constitutes the center along which all pistons and their rods revolve in a balanced centrifugal condition, with no reversal of direction of pull on the connecting-rods. Fig. 13 is a perspective view of two of the self-aligning bars with annular rings, which, when assembled, are mounted on inner creeping sleeves.

As the engine is of the two-stroke cycle type, the cylinders are fired in rotation one after the other. This gives a constant torque and permits of the use of a very simple ignition device; for example, in a six-cylinder engine a two-point magneto may be used, driven at a speed of three to one with a single wire leading to a brush-holder coöperating with spaced contacts connected to the respective spark plugs in each cylinder. The brush engages these contacts in rotation. The spark plugs are directly in front of the incoming gas, which assures perfect scavenging and allows the motor to be throttled to a very low speed and at the same time insures that the spark plug shall be in the region of the fresh fuel gas. A diagram showing the inlet and exhaust cycles of the motor and the section of the box cam that closes the exhaust ports in each revolution is shown in Fig. 14.

Following are given data of the more essential features of this engine: Number of cylinders, 6, having six double-acting pistons utilized both as power pistons and pumps; bore of working cylinder, equivalent in area to a 4⅝-in. conventional piston; stroke, 4 in.; area of piston, 16.7 sq.in.; area of pump, 23.76 sq.in.; connecting-rod crank ratio, 4 to 1; bore of crank case, 10¼ in.; over-all diameter of motor, 26 in.; over-all length of motor, 24 in.: two-spark magneto, driven 3 to 1, giving six sparks per revolution; approximate weight of motor, 2 lb. per hp.; compression, from 90 to 100 lb. per sq.in.; positive system of force-feed lubrication.

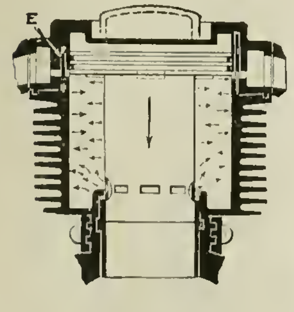

FIG. 5. PISTON PORTS AND CYLINDER

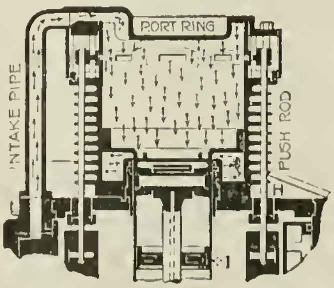

FIG. 6. PISTON AT INNER END OF CYLINDER

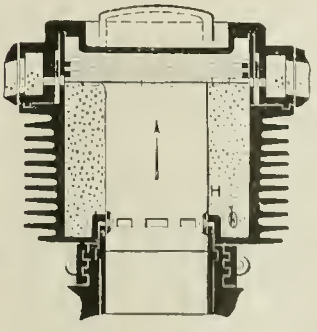

FIG. 7. PISTON AT EXHAUST AND RELEASE

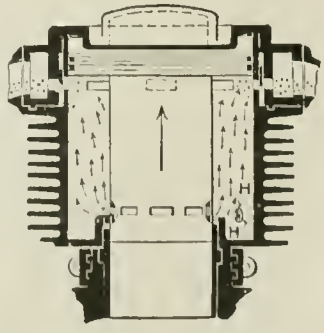

FIG. 8. INTAKE PORTS OPEN

The engine is started by turning the switch of the magneto and pressing the button of the self-starter. When the engine is stopped by turning off the switch all the cylinders are charged with fresh fuel from the inner chamber and are ready for the next operation. The engine can be started with a coil and battery if desired. It is made reversible by simply adding a sleeve to reverse the inlet and transfer ports. The engine is practically fool proof for the reason that there are no adjustments to be made.

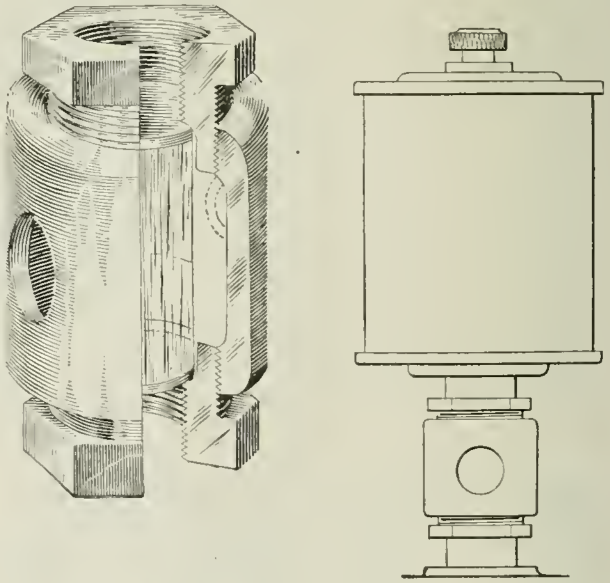
Sight Feed for Oil Cups

By F. W. Bentley, Jr.

The lower, or sight-feed, portion of heavy oil cups is frequently broken, due to lightness in the constructtion of the average frame holding the glass—heavy enough, of course, to support the lubricator under ordinary circumstances, yet too easily broken in case of accident. The lower end of the oil cup or lubricator can in most cases be retapped and fitted again to give service, but the sight-feed glass retainer or receptacle is a hard thing to repair and it is difficult to get something to work as a substitute.

The illustration shows how a sight-feed arrangement can be made out of two pipe-reducing bushings, a coupling and a piece of tubular glass. Most reducing bushings have an unthreaded recess on the inside, the threads not extending entirely through, which affords an excellent shoulder for retaining the glass at both ends. A hole is drilled through the coupling of approximately the same size as the outside diameter of the glass. The two bushings can be screwed firmly down into the coupling and the distance measured, which will give the necessary length for the glass. The glass can be set with cement or putty.



OIL-CUP SIGHT FEED MADE OF PIPE FITTINGS

Where a new fitting cannot be secured or a cup having no sight feed is used, this little kink can be resorted to and will afford a strong and easily constructed sight feed. The one shown is of a ¾-in. coupling for ½-in. connections, a short piece of ¾-in lubricator glass being set in place with cement.

Operation and Maintenance of Elevators—Care and Lubrication

BY R. H. WHITEHEAD

Attention is called to the fact that elevator machinery, like any other equipment, must be given proper care. Certain important features in the maintenance, care and lubrication of modern drum-type elevator machines are pointed out.

EVERY operating engineer knows the necessity of careful maintenance of machinery to avoid trouble and get the proper results. The writer finds that elevator machinery is very likely to be neglected. Sometimes this is because the elevator is cared for only when there is nothing else to do and this happens at infrequent intervals, and in other cases it is due to lack of familiarity with the equipment. The only proper way to maintain an elevator is to make thorough inspections of the various parts of the installation at regular intervals. Several elevator manufacturers furnish just such service on what is termed a "Maintenance Contract." In the following, attention is called to certain features in the maintenance and care of the drum type of elevators.

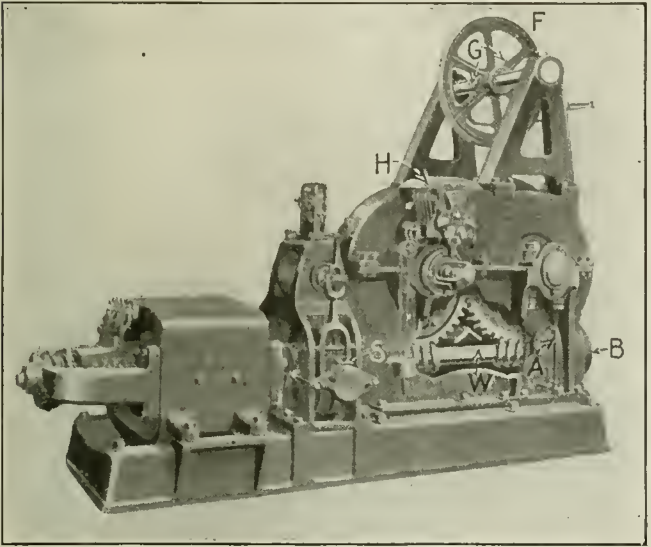


FIG. 1. DOUBLE-GEARED ELEVATOR MACHINE

1. Open the main-line switch and take care that no one closes it, so as to prevent accidents when preparing to clean, oil or repair any part of the machinery. Keep all parts of the machine and controlling device, motor room and pit clean; a pair of hand-bellows should be used to blow the dust from the motor, controller and other parts of the apparatus that cannot be conveniently reached. Where possible, the parts should be wiped clean, and cement and brick dust not allowed to get on the machinery and into the lubricants.

2. Self-oiling motor bearings have rings, which should always turn freely, and the oil chambers must be kept sufficiently full of motor-bearing oil to insure the oil rings dipping into it. Attention should be given the rings while the machine is running to see that they carry the lubricant from the oil well to the top of the shaft.

3. Use only worm-gear lubricant for the worm and gear and keep the gear case filled to a point just above the top of the wormshaft *W*, Fig. 1; the standpipe *A* on the side of the gear case should be used to determine the height of the oil. To remove sediment and grit, drain the oil from the gear case three or four times a year and refill with fresh lubricant. If the oil gets below the wormshaft level, the bearings will seize and expensive repairs will be necessitated. Do not use dirty or poor lubricant, as the worm and wormwheel will wear quickly, and for that reason it is poor economy.

4. The wormshaft bearings *B* and *B*, Figs. 1 and 2, are automatically oiled from the gear case, and oil should be allowed to drip slowly through the wormshaft gland *C*, Fig. 2, to insure perfect lubrication of the inboard bearing. Use a pan to catch the oil, but do not use the oil again without straining and then only once.

5. The wormshaft stuffing-box *D*, Fig. 2, must be kept packed with square-braided flax packing. The gland-adjusting nuts *E* must be tightened evenly to prevent binding of the wormshaft, but not tight enough to prevent the drip of oil.

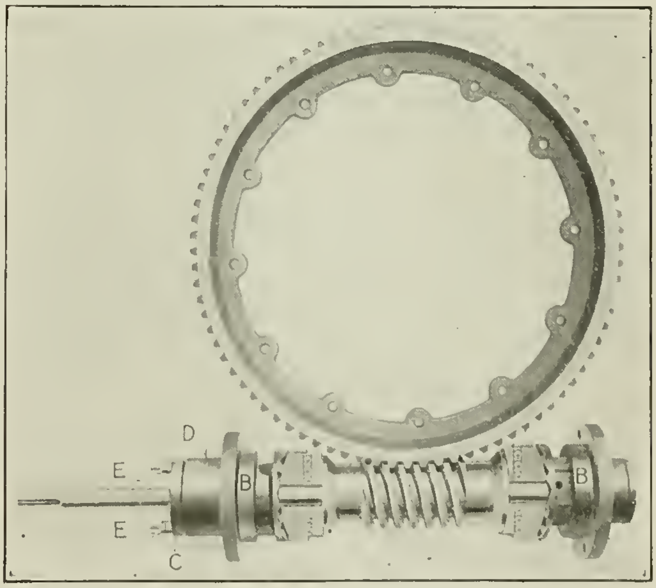

FIG. 2. SINGLE WORM AND GEAR SHOWING BALL THRUST BEARING

6. Drumshaft bearings should be lubricated every day or be provided with automatic grease cups or lubricators.

7. All parts of the governor must be kept well lubricated so that they work freely and easily, and this includes the tension sheave in the pit.

8. Vibrator sheaves *F*, Fig. 1, should be lubricated by means of grease cups *G* filled with compression-cup grease and sufficiently compressed to properly feed the lubricant. If automatic grease cups are used, be sure

that the cups feed. Remove the entire cup occasionally and see that grease feeds slowly through its nipple.

9. Overhead-sheave bearing boxes should always be packed with compression-cup grease. The grease must be pushed against the shaft once or twice a week, as sufficient heat is not generated in the bearings to cause the grease to run as in the case of continuously operated machinery.

10. Ropes should occasionally be coated with elevator-rope compound to preserve them and prevent rusting. This may conveniently be applied with a brush.

11. Safety devices on the car frame and safety plank under the car should be examined at frequent intervals and all working parts kept clean, well lubricated and free from rust.

12. On the guides use guide lubricant and occasionally clean down the guides with kerosene to remove grit. If lubricators are used, see that they are kept clean and filled.

13. Adjust the brake springs *S*, Fig. 1, to properly hold the car under maximum load and to give a smooth stop. Set the brake shoes so that they just clear the brake drum when released. If a piece of thin paper can be passed between the shoes and brake drum, the clearance is sufficient. In case the clearance of the brake shoes is too great, they should be reset to give the proper lift. The brake drum and brake shoes must be kept dry and clean. Under no circumstances allow oil on the brake drum or brake-shoe lining. In the case of an alternating-current machine the brake-magnet case must be kept well filled with brake-magnet oil. When necessary to remove the brake shoes for cleaning or repairs, the empty car should be left at the top landing with the counterweights securely blocked up in the pit. Oil the brake-lever pins frequently where oil holes are provided.

14. On direct-current machines, to prevent sparking at the commutator, when adjusting or renewing the brushes, fit them to a full bearing with a strip of fine sandpaper—never use emery cloth. This may be done by placing the paper between the commutator and the brush (sand side against the carbons) and drawing it back and forth by hand, at the same time keeping the smooth side against the surface of the commutator. The carbons must always project beyond the holder so that the latter will not bear on the commutator. Brushes should be staggered to distribute wear evenly on the commutator. In case the commutator becomes rough, it may be made smooth by holding a piece of fine sandpaper—never emery cloth—against the surface while the machine is running, after which it should be wiped clean. A canvas pad—never use waste—should always be used for cleaning the commutator. Sandpapering the commutator should be avoided as much as possible. Polishing when new with canvas, after being sure that the brushes do not spark and are bearing properly on the commutator, brings about the burnished finish which renders the commutator less liable to damage.

It is most essential to keep the commutator free from dirt and oils. This applies to the head of the commutator and the mica insulating ring at the base of the bars, as well as to the surface of a commutator.

On alternating-current machines keep the collector rings on the motor clean and free from dirt and oil and see that all brushes have a good even bearing on rings.

15. The contacts of the slack-rope switch and of the hatchway-limit switches should be frequently cleaned.

16. The car should be frequently tried on the atuomatic stop to see if it is properly adjusted, as the automatic is thrown out of adjustment through the stretching of the ropes. Frequently remove the cover *H*, Fig. 1, of the automatic switch on the machine and clean the contacts thoroughly and oil its mechanism.

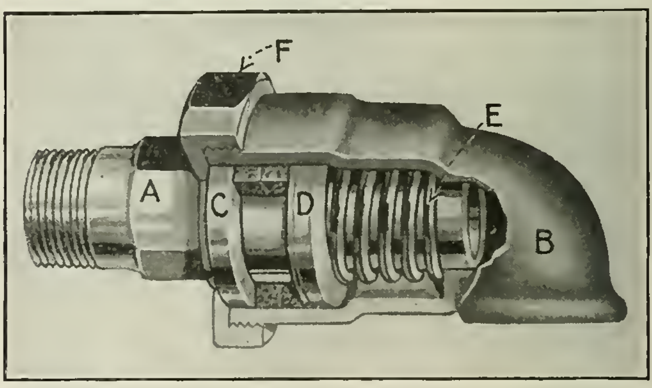
17. The ropes should be shortened as may become necessary and never allowed to lengthen to such an extent that the car will not open the hoistway-limit switch at the top of the hoistway before the counterweights bottom in the pit.

18. Controller parts should be kept clean and well lubricated so that they work freely. Keep the metal and carbon contacts on the controller clean and free from pits and blisters. They should be frequently dressed with sandpaper and have a good even bearing when in contact.

Although the foregoing was written as applying to Otis Elevator Co.'s machines, nevertheless the major portion of it applies to elevator machinery in general.

Tuxeda Swing Joint

Swing joints are made in various types, but to be really serviceable it is necessary that they be leakproof. A swing joint with this quality appears to have been found in the Tuxeda, manufactured by Franklin Williams, 39 Cortlandt St., New York City. The joint is made with a male and a female member, *A* and *B*.



SEMI-INTERIOR VIEW OF TUXEDA SWING JOINT

The male member has a collar *C* against which the packing is forced by the pressure exerted upon the loose collar *D* by the compressed spring *E*, as shown in the illustration. The joint is held together by a shoulder nut *F*, which screws on the outside of the *B* member. The spring *E* automatically compensates for wear of the packing and keeps the joint tight. When worn out, the packing is easily removed and replaced. This joint is made in standard sizes from $\frac{1}{8}$ to 3 in., but larger sizes are available.

Water Commissioner George C. Andrews of Buffalo, N. Y., reports that during the month of April, water pumpage was reduced millions of gallons with a saving of 415 tons of coal, worth $1850. Pitometer experts have been at work searching for underground leaks which do not show on the surface of the streets. Several large leaks have been located and repaired.

Pipe-Line Transportation of Coal

Some of the chief features of a proposed plan for increasing the transportation facilities of the United States, preventing fuel famines, and saving a billion dollars a year.

THE pressing necessity for an ample supply of coal to meet the greatly augmented demands of the war industries and at the same time provide for all normal requirements in the matter of heating, lighting and power has focused an extraordinary amount of attention on the present-day methods of distributing and utilizing fuel. As a result, numerous schemes have been suggested with a view to eliminating wasted effort and thus ameliorating the difficulties that at present confront the coal consumer.

One of the most ambitious of these plans is that proposed by Farley G. Clark, of Niagara Falls, N. Y. Although it relates specifically to bituminous coal, its application would save both hard and soft coal and would relieve the railroad situation, at the same time producing a stupendous saving of money. The plan contemplates:

1. The preparation of bituminous coal at the mines by pulverizing and the removal of a large part of the impurities by washing.
2. The transportation of the prepared coal mixed with water through pipes laid along railroad lines.
3. The storage of such coal in quantity, properly protected against deterioration, near the centers where it is to be used.
4. The utilization of pulverized coal in locomotives, for steam generation and for general use.
5. The manufacture of byproduct coke and gas at or near large metropolitan districts, the coke to be used in metallurgical processes and mixed with pulverized coal and tar as briquets to replace anthracite, and the gas to replace soft coal, water gas and anthracite.

USE OF WATER TO FLUSH COAL THROUGH PIPES

The chief feature of this scheme is the pumping of the prepared coal through pipe lines from the mines to centers of distribution. Water is used as the vehicle for carrying the coal, because it is cheap and abundant. The coal as it comes from the mine is sent through crushers, in which it is reduced to ¾-in. lumps, and then passes by gravity to the pulverizers, in which it is reduced to such a fineness that all of it will pass through 100-mesh and 50 per cent. through 200-mesh.

Magnetic and gravity separators remove impurities and the coal is then run into jiggers, in which it is thoroughly agitated with water, resulting in the dissolving of most of the sulphur and some of the other impurities. Centrifugal separators then remove most of the water, and the fairly dry coal is washed and delivered to wet grinders, from which it issues as a slime. The slime passes over concentrating tables, where it is divided into two grades, one to be sent to the boiler room for immediate use and the other to be sent to the pipe-line pumps.

The slime to be pumped is mixed with fresh water in agitating tanks, from which it is drawn by centrifugal pumps and forced through the pipe lines. The mixture in the pipes consists of from 30 to 40 per cent. of water and from 57 to 67 per cent. of coal, the remainder being ash and other foreign matter. The entire cost of this preparation will not increase the cost of the coal more than $1 a ton in extreme cases, and in some cases only about 25c. a ton.

The pipe lines are run along the rights-of-way of the railroads and are placed underground wherever possible. The main lines are supplied by branch feeders from the producing centers and branch distributors lead off to the distribution centers. A network of such pipe lines, with suitable storage reservoirs, coke ovens and briquetting plants would handle 70 per cent. of all the bituminous coal mined.

PUMPING STATIONS AND STORAGE RESERVOIRS

Pumping stations at intervals of 12 miles or more would need to be provided on the main pipe lines, and at each station an emergency reservoir would have to be supplied to allow the pipe line to be drained to prevent freezing or to make repairs. At the distribution plants it would be necessary to have large storage reservoirs, one for each grade of coal pumped. These accumulations would tide over any reasonable emergency that might arise and would enable a demand for a certain grade to be met immediately.

At or near the distributing plants the byproduct coke ovens or coal-gas plants would be erected. These would convert the coal sludge into coke and gas and recover the usual byproducts. The gas would be piped through mains to supply the district. The coke would be shipped to foundries and furnaces, while the breeze could be mixed with pulverized coal and briquetted.

It is estimated that the cost of pumping the coal would be comparatively low. A pipe line 20 in. in diameter would handle 25,000 tons per day at a cost of 50c. per 1000 ton-miles of actual coal transported, this figure including operation, maintenance and 10 per cent. interest on investment. The present rate for transporting coal by car is more than $4 per 1000 ton-miles.

Mr. Clark's plan does not contemplate the immediate changing over of all boiler plants so as to use dry pulverized coal. That is considered as a possibility to be reached eventually. For the present the pipe-line coal would be used in boiler furnaces as they exist or as they could readily be adjusted without seriously disturbing industries. The coal would be deprived of moisture to 10 per cent. or less by centrifugal driers and spread over the grate by suitable devices; or, it may be burned by the existing types of underfeed and chain-grate stokers. The moisture remaining in the coal will hold the fine particles together until the volatile matter is driven off and the coke remains. As there is very little ash or impurity in the fine coal, the tendency to clinker will be practically eliminated. The ash in pipe-line coal would never exceed 3 per cent. and the average would be much lower.

The railroads distribute over 80 per cent. of all coal and this constitutes 35 per cent. of the total freight handled. The pipe-line distribution of coal would reduce the freight congestion on the railroads by relieving them of at least one-fourth of their present burden, thus enabling the equipment to be used for other commodities.

The greater part of the domestic coal consumed is anthracite. Under the pipe-line system, heating and cooking would be carried on largely by the use of gas from coke ovens and gas plants burning pulverized coal, supplemented by the use of briquets and anthracite, with a resultant enormous saving.

The estimated saving in tons of coal in various lines is given in Table I, and the value of the saving is given in Table II.

TABLE I. ESTIMATE OF COAL SAVING

	Used in 1917 Millions of Tons			Possible Saving Millions of Tons		
	Bit.	Antb.	Total	Bit.	Anth.	Total
Railroad	180	5	185	100	3	103
Steam	195	20	215	20	15	35
Coke	75		75	—45		—45

Bunker	20		20			
Miscellaneous	20	5	25	5		5
Totals	540	80	620	105	53	158
Per cent. saved				17.4	66.2	25.4

TABLE II. VALUE OF COAL SAVING

Bituminous railroad coal, 100 million tons at $4	$400,000,000
Bituminous general-use coal, 5 million tons at $6	30,000,000
Anthracite railroad coal, 3 million tons at $3⅓	10,000,000
Anthracite general-use coal, 50 million tons at $8	400,000,000
Total	$840,000,000
Substituting $6 coal for oil at $4 per bbl., saving $2 per bbl., on 20 million bbl	40,000,000
Substituting byproduct for coal and water gas, saving 25c. per 1,000 cu.ft. on 800 billion cu.ft.	200,000,000
Total value of saving per year	$1,080,000,000

This saving of over a billion dollars a year is necessarily only an estimate, but it is based on conditions with regard to which reasonable predictions can be made. Moreover, it does not take into account the relief to the railroads and to industry in general, while the value of storage at the points of consumption cannot be reduced to dollars.

In developing his idea, Mr. Clark has counted on objections from various quarters. For example, mine workers and owners may find fault with some provisions of the scheme, particularly those that relate to the recovery of a greater percentage of the coal from the earth, even at the risk of including more dirt, since the subsequent washing and grinding removes the impurities.

OBJECTIONS FROM RAILROADS AND OTHERS

The railroads may be expected to object to a change that would remove a large part of their freight business; but with the increased demand for transportation of other materials than coal, it would seem as though the net result would be to the advantage rather than the disadvantage of the railroads.

The coke industry might interpose some objections, because the Clark plan contemplates the use of byproduct ovens only, and the obliteration of the beehive type. Some engineering objections might be raised in connection with the utilization of pipe-line coal, but it is believed that there are no obstacles of an engineering character that cannot be overcome.

Of course, the complete adoption of a plan of this magnitude would cause considerable change in the methods of utilizing coal, and expense would be incurred; but for the sake of so great a saving, it would be proper to go to considerable initial outlay. The fuel problem must be settled sooner or later, for it grows more acute each year, and such plans as the one proposed by Mr. Clark indicate a healthy interest in the solution of this important matter.

Superheat in Forced-Draft Stoker Installations

By H. R. Greene

In designing boiler plants, as in the case of all engineering installations, there must be taken into consideration by the engineer, the relation between the first cost of the various apparatus and their performances. Coal is much more expensive than formerly and, unquestionably, in this country within a short period of time we shall be compelled to select all the component apparatus with a view to the highest efficiency in the production of power in the complete installation. This being the case, it is axiomatic that the economical performance of various apparatus is, except in extreme cases of excessive cost and where certain predetermined performances must result regardless of economical operation, the determining factor in the decision as to selection.

In the competitive-sales problem of multiple-retort stokers, the economical operation of the necessary auxiliaries is of the greatest importance in determining the advisability of selection in comparison with natural-draft stokers. This is necessary to justify the high first cost of the former and also the excessive additional expense of the forced-draft equipment to supply air for predetermined results exclusive of the higher combined efficiencies obtained and the net economical results of the boiler-stoker combination. In the large power stations where great fluctuations of load occur, the forced-draft system of air supply must always prevail, on account of the elasticity required, but in manufacturing plants operating under nonvariable loads, the sales problem becomes one of comparative efficiency, all things being taken into consideration.

Here is where superheating is of value. We may compare the steam necessary for stoker driving as about equal between the forced- and natural-draft systems; but all the steam necessary for the forced-draft equipment must be charged against the efficiency of the stoker requiring it. Superheating is, of course, raising the heat of saturated steam above the temperature normal to its pressure. We then have a gaseous element, following the laws of perfect gases, and no moisture can exist while superheat remains; thus pipe and cylinder condensation losses are eliminated.

The problems of proper packing and lubrication in reciprocating engines have been largely solved, and with turbines lubrication is not necessary and packing complications have been satisfactorily overcome.

As we use both turbines and simple engines for fan prime movers and the latter for stoker driving also, it is interesting to note that the saving in the former at 100 deg. F. superheat would reach approximately 8 to 10 per cent. and in the latter over 12 per cent. The importance of such savings in water rates can readily be realized in computing comparative net efficiencies with natural-draft stokers in competition.

Useful Kinks for Engineers

By Frank R. Williams

The so-called self-marking paper for indicator diagrams and other uses is a plain chemically coated paper that is easily marked by the touch of a plain brass or aluminum point. It is much used for taking indicator diagrams instead of the common paper card and lead pencil, which are often troublesome and unsatisfactory. The paper can be bought in large sheets or it may be prepared easily and cheaply at home as wanted, by taking ordinary zinc white, which can be bought at any drug store or paint shop, and mixing with common thin mucilage into a thin paint and lightly coating the paper with it. When dry it may be used as ordinary indicator-card paper, using a brass or aluminum point instead of a lead pencil.

It is often desirable to make holes in glass, but few persons know how to do this. It may be done easily and conveniently without special appliances in the following manner: For small holes take an ordinary three-cornered file, such as is used for sharpening saws, and grind all flat sides to a three-cornered sharp point. Then put some spirits of turpentine on the glass and rotate the drill with a moderate pressure. One will be surprised at the slow but satisfactory progress that will be made through the glass. The cutting edge of the drill should be kept wet with turpentine while cutting. The old receipt says add camphor dissolved in spirits of turpentine; but I find that the drill works well without the camphor.

To make large holes, take a copper tube the size desired and rotate it upon the glass with moderate pressure, and keep it wet with fine emery and oil. It is best to cut from both sides, meeting in the center, but one should be careful to keep the drills rotating freely and easily, as any pinch or jam may break the glass. Finish the hole with a half-round file wet with spirits of turpentine.

An ordinary twist drill can be used to drill glass, but it must be ground with considerable clearance, both on the cutting edge and on the circumference, as the least pinch will break the glass. Keep the drill wet with spirits of turpentine.

Engineers do more or less soldering, and a strong solder can be had by using pure tin. It will be about twice as strong as common tin and lead solder and never turns black or disintegrates. I have used it exclusively, where greater strength is required than is obtained with ordinary solder and where brazing or silver solder would not do because of the high temperature.

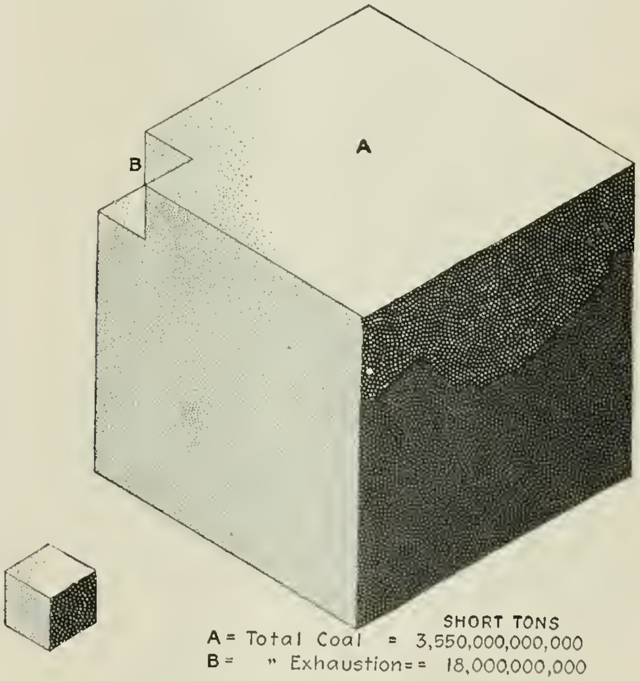
A safe liquid flux for electrical soldering is made by dissolving rosin in alcohol. A similar paste flux is made by taking chloride of zinc, which can be bought at any drug store, and rubbing it into a thick paste with common vaseline or petrolatum.

Worn or warped rubber valves may be refaced and made to do additional duty by tacking a sheet of sandpaper on a smooth board and, with the hands holding the valve flat and steady on the sandpaper with gentle pressure, rubbing the valve back and forth. This will gradually cut down the rubber so as to make a true face.

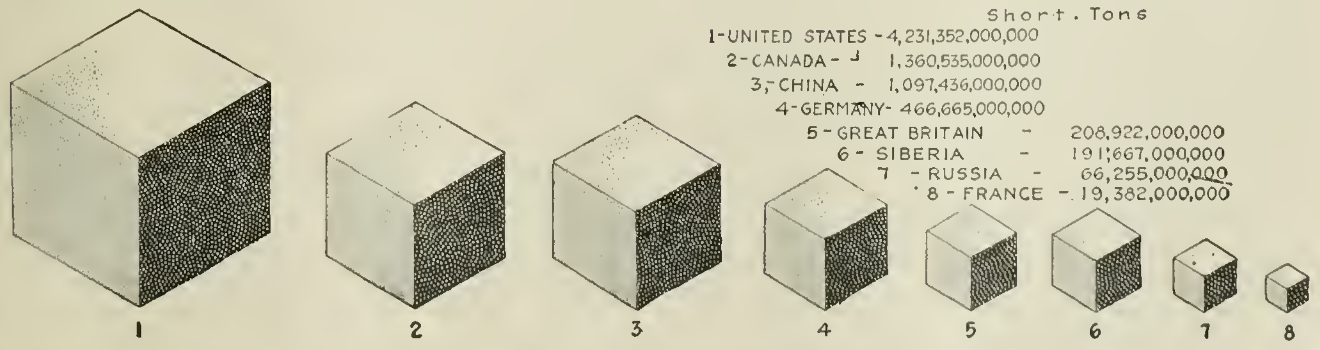
To remove broken taps or drills, wet for a few hours with ordinary muriatic acid which will slightly dissolve the steel and make the broken tool smaller, thus making it more easily removable.

The Coal Supply

The illustrations below are from a paper by R. H. Fernald before the Engineers' Club of Philadelphia. With their aid one is able to visualize the coal supply of the world and to get a good conception of the coal available in the United States compared with what has been used up to date.



TOTAL AVAILABLE COAL IN UNITED STATES AND EXHAUSTION TO CLOSE OF 1917



COAL RESERVES OF THE WORLD AND THEIR DISTRIBUTION

Plastic Refractory Boiler Baffles

The principal loss of heat from a boiler furnace is in the flue gases, and is measured by the product of their weight, specific heat and excess of temperature over atmospheric. High temperature of gases may be due to their coming in contact with too little heating surface, to coatings of soot or scale on the heating surface which prevent the absorption of heat from the gases, but most commonly it is caused by defects in the baffling.

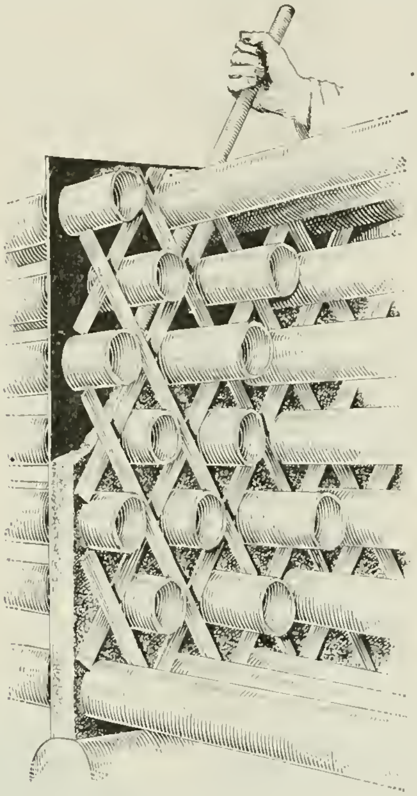


FIG. 1. PLACING THE MATERIAL BACK OF CRISSCROSS SLATS

Baffles may be improperly located, producing dead spaces where the gases do not circulate in the tube banks of water-tube boilers, or the baffling may not provide for a sufficiently high velocity and long path of the gases of combustion.

Defective baffling is the most common cause of high chimney temperatures. The baffles may have fallen down, or bricks or blocks may have slipped out from between the boiler tubes, allowing the short-circuiting of a large amount of gas.

Baffles for water-tube boilers have in the past consisted of tile, bricks or blocks of refractory material fitted in between the tubes. In cross-baffled boilers these tiles are introduced between the tubes by springing the latter, and naturally do not always form tight joints with one another or with the tubes, especially after the latter have warped or sprung, as they invariably do in service. It is also difficult to insure that blocks will remain where they are placed and will not slip or fall, leaving large openings. Owing to the manner in which baffles are inserted in boilers, it is almost impossible to cement them together; moreover, the difference in expansion and contraction of the boiler and baffling would break the joints apart.

The illustrations show how jointless, gas-tight baffles can be made by the use of a refractory known as plastic firebrick and manufactured by the Betson Plastic Fire Brick Co., of Rome, N. Y. This material is compounded of refractory substances so prepared as to practically eliminate expansion and contraction with changes in temperature.

In forming a cross-baffle for a water-tube boiler of the B. & W. type, the ordinary cast-iron baffle plate is used as one side of the mold, while the other is made by thrusting slats in through the diagonals between the tubes, as shown in Fig. 1. The plastic material is then poked down through the diagonals to fill the space between the cast-iron baffle plate and these slats. It is sufficiently plastic so that it can be forced out sidewise around the tubes, fitting the latter snugly.

When this work has been completed, the boiler is fired up slowly, the crisscross of slats burns out, and the plastic material is dried and vitrified in place. This operation occupies only a few hours, after which the full load may be put upon the boiler. Inasmuch as the boiler comes up to full steam pressure before the material is thoroughly set, the expansion of the metal pushes away the soft material to the position it should occupy when the boiler is hot, and while the boiler will draw away from the material in cooling off again, the baffles will fit tightly when the boiler is under steam.

In forming a longitudinal baffle, Fig. 2, blocks of wood are placed in between the tubes, above and below the space which it is desired that the baffle shall occupy, thus confining the plastic material, which is shoved in from the side in the case of baffles in the middle of the tube bank or from underneath or overhead in the case of the baffles at the bottom or top of the tube bank.

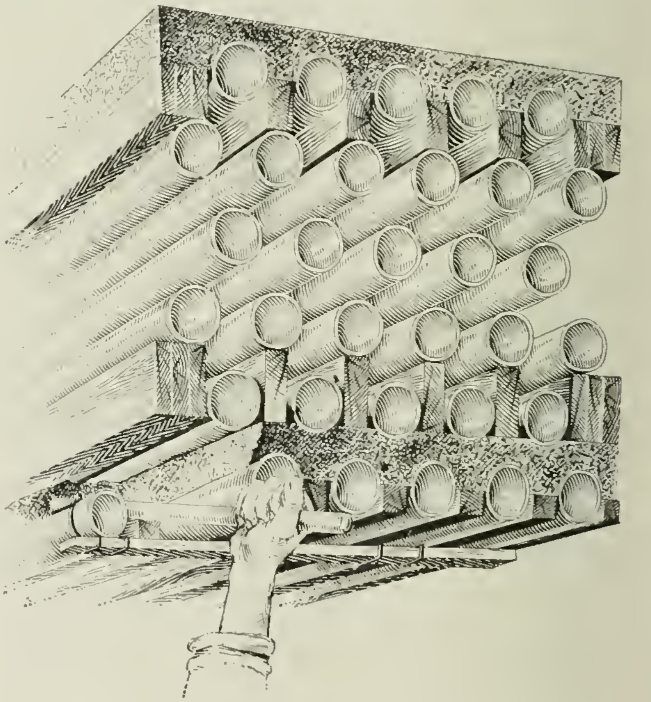

FIG. 2. HOW MATERIAL IS PLACED FOR HORIZONTAL BAFFLES

Where this material is used, there is no restriction upon the shape or size of the baffle, and the latter can therefore be arranged in any form desired. In cross-baffled boilers, for example, it is becoming the practice to slope or incline the baffles so that the gas passage will contract progressively from the point where the gases enter the tube to the point where they leave, in order to maintain a uniform gas velocity, in spite of the shrinkage of gas volume with cooling. This is easily accomplished with the plastic material.

This material also finds use as a substitute for special forms of bricks or blocks; as for example, where the front headers of horizontal water-tube boilers rest upon the front arch. It is used for lining furnace and combustion chambers, including front arch, side walls, bridge-wall, rear arch, etc.

Refinite Water Softener

When boiler-feed water contains a scale-forming element, two conditions must be met—the boiler shell and tubes will have to be cleaned of scale at intervals, according to the quantity of scale formed, and if the formation is to be prevented the water must be treated before it goes into the boiler.

Numerous systems of water-softening plants are employed for boiler-feed water, some being installations of considerable size, and are generally used with steam plants of medium and large capacity. A system designed for both small- and large-capacity power plants is manufactured by the Refinite Co., Omaha, Neb., and is known as the Refinite water softener.

The illustration shows a 60-in. water-softener system, consisting of a closed tank in which the softening mineral bed of filter gravel is placed. Raw water enters the softener tank through the pipes *A* and *B* and, striking a baffle plate, is sprayed over the mineral softening bed. The treated water leaves the softener through the pipe and meter *C* after it has passed through the Refinite mineral bed.

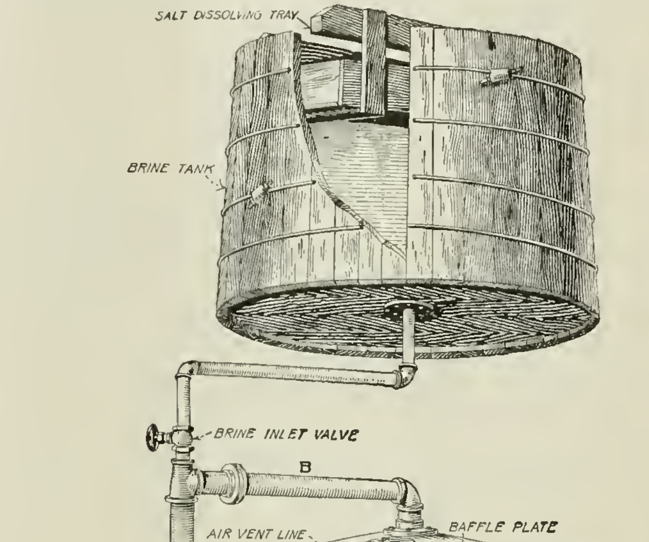
The operation of the system depends upon this mineral bed, which is composed of a clay product having zeolite properties. It is put out in a form suitable for the commercial use of softening water, and the mineral is furnished with the apparatus, which, as shown, is constructed much the same as the ordinary pressure filter. The mechanical operation of softening water is one of simple filtration, or just passing the water through the mineral bed, the same as water is passed through a sand filter. After a time all the original sodium in the Refinite will have been given up in this exchange. When this occurs, the softening action ceases, but it is not necessary to replace the mineral or to remove it from the softener container.

By a reverse action, called regeneration, in which ordinary salt is the reagent, the softening action of the Refinite may be restored. Common salt, sodium chloride, is dissolved in water in a tank, and the brine run into the softener and allowed to stand therein for a few hours, after which the softener is ready for the next run.

Hardening salts in water vary considerably, and can be actually determined and weighed. A pound of Refinite mineral has the ability to take up a certain amount of these hardening salts by actual weight. Therefore, the capacity of one pound of the mineral in gallons would depend on the weight of the hardening salts in the total quantity of water handled.

One pound of Refinite mineral has the ability to take up 54 grains of hardness. If the water contains 18 grains per gallon, one pound of Refinite mineral will handle three gallons, and the time required for the action is ten hours. From three-fourths of a pound to one pound of salt is required to eliminate each grain of hardness in a thousand gallons of water by the Refinite process. If the water contains 18 grains of hardness, for instance, 18 lb. of salt would be required to treat 1000 gal. The average cost of the salt used is about a half-cent per pound.

Thus the capacity of any sized softener in which a stipulated amount of mineral is used, depends on the hardness of the water treated. If the water is 18 grains hard, a certain number of gallons can be handled. If the water is only 9 grains hard, twice the amount can be handled, and the capacity in any case is inversely proportional to the hardness in the water.



SEMISECTIONAL VIEW OF THE REFINITE WATER SOFTENER

It is necessary, therefore, to regenerate after each capacity of softening has been run. If the machine is designed to handle 10,000 gal. in 10 hours, it is regenerated after each 10-hour run, and the time required for regeneration is usually from 8 to 10 hours. The operation takes place at night while the softener is not in operation.

Questionnaire Which Owners of Power Plants Will

Questionnaire for Power Plants. General Information To Be Supplied by the Owners. Not to Be Used for the Rating of Plant

Date of Report..............

Name of company, concern or owner................

Address of Central Office..........................

Name and location of plant inspected................

Character of product or service.......................

STATIONARY BOILERS

WATER-TUBE BOILERS

		Kind of Draft			How Fired			
Number	Hp.	Nat'l	Forced	Induced	Stoker	Hand	Total Hp.	Remarks

FIRE-TUBE BOILERS

		Kind of Draft			How Fired			
Number	Hp.	Nat'l	Forced	Induced	Stoker	Hand	Total Hp.	Remarks

MOVABLE BOILERS*

Number	Hp	Type	Remarks

Kind of coal	....	Bituminous	Semibituminous	Anthracite
Size.......	....	..	.. ..	....

Tons of coal of 2000 lb. used during twelve months ending May 1, 1918...................

Months of operation of plant during the same year......... .....

Approximately what percentage of live steam is used for:

	Winter Per Cent.	Summer Per Cent.
(*a*) Making power ...		
(*b*) Heating building		
(*c*) Process work..		

Is purchased electric power used? ....

If so, how many kilowatt-hours consumed during twelve months ending May 1, 1918? ....

RECORDS

Are records kept to show any of the following information? Answer "Yes" or "No" in table.

	By Shift	Daily	Weekly	Monthly
Water evaporated by boilers..				
Coal consumed by boilers........				
Flue-gas analysis ...				
Electrical output or consumption kw.-hr				

ENGINE EQUIPMENT

STEAM UNITS—ENGINES, TURBINES, PUMPS

			Rating				
Type	No.	Initial Pressure	Hp.	Kw. or Gal. Per Min.	Condensing	Noncondensing	Type of Valve Gear

Note to Owner: If sufficient space is not available in the questionnaire, please attach an extra sheet with the additional information.

RECOMMENDATIONS BY THE FUEL ADMINISTRATION

That provision be made for weighing and recording of the fuel used each shift or day.

That feed water be heated and measured.

That provision be made for an adequate supply of air to the fuel and convenient means provided for the measurement and control of the draft.

That provision be made to keep boiler surfaces clean inside and out.

That the grates be in good repair, that settings, breeching and access doors be free from air leakage, and that boiler surfaces wasting heat be covered with insulation.

That the surfaces of steam piping, drums and feed-water heaters which waste heat or steam by radiation be properly covered with insulating material.

That exhaust steam be utilized wherever possible, to the exclusion of direct steam from the boilers. The plant should be so designed that no more exhaust steam will be produced than can be efficiently utilized in heating or process work.

That a competent man in the plant be detailed for the work of fuel conservation in the boiler and engine rooms.

That a competent man or committee be detailed for the work of fuel conservation in the building or shop outside of the power plant.

---

* In the rating of the plant movable boilers will be considered separately. The questionnaire does not call for information regarding movable boilers except as per above table. The influence of movable boilers on the rating of the plant will be left to the judgment of the Administrative Engineer.

Be Asked by the Fuel Administration to Fill Out

Outline of Standard Questionnaire Covering Operation of Steam-Power Plants. Questions to Be Marked to Form Basis of Rating of Plant

(a) FUEL: Value of question, 9. Mark rec'd......

Question 1. What provision is made for weighing fuel used each shift or day?

Question 2. What records are made of fuel used each shift or day?

Question 3. What grate surface is in use each shift, exclusive of banked fires?

Question 4. Total coal used each shift exclusive of banked fires?

(b) WATER: Value of question, 15. Mark rec'd.....

Question 1. What provision is made for heating and continuous measuring of feed water (check answer in table below)?

Heating	Means Used for Measuring
Open feed-water heater...........	....
Closed feed-water heater	....
Exhaust steam	....
Direct steam	....
Waste heat economizer...........	....

(c) AIR SUPPLY: Value of question, 12. Mark received ....

Question 1. Are means provided for measuring the draft over the fire?

Question 2. Are means provided for determining the excess air by flue-gas analysis?

Question 3. Are dampers provided for equalizing the draft in the furnaces?

Question 4. Is there a convenient means for regulating the draft by main or uptake damper?

Question 5. Is there an automatic damper regulator in working order?

(d) CLEAN HEATING SURFACES: Value of question, 12. Mark received ....

Question 1. What provision is made for keeping soot and ashes from boiler-heating surfaces (mark answer in table below)?

Steam lance for blowing soot by hand......
Mechanical soot blower ....
Brushes or scrapers.. ....

Question 2. How often are the soot and ash cleaned from the boiler-heating surface?

Question 3. What provision is made for keeping scale and sediment out of the boiler (check answer in table below)?

Chemical treatment of feed water in the boiler.... ....
Chemical treatment of feed water outside of boiler.... ....
Filtration of feed water in open feed-water heater .. ..
Filtration by means of feed-water pressure filter. ... .
Other means............. ....
Water is free from scale or sediment without treatment ....

Question 4. What means are used for removing scale from the boiler?

Hand .... Mechanical ....

(e) BOILER AND FURNACE SETTING: Value of question, 20. Mark received..............

Question 1. Are the grates warped, broken or otherwise defective?

Question 2. Check air leaks observed, as follows:

Leaks in boiler setting
Openings between boiler and setting ......
Badly warped fire-doors.. ....
Badly warped cleaning or access doors ......
Leaks around blowoff piping ....

(f) INSULATION: Value of question, 7. Mark received ....

Check any of the following items where saving could be made by covering surfaces with insulation:

Exposed drums of boilers ......
Exposed shells of boilers ......
Steam piping in boiler room ......
Steam piping in engine room ......
Feed-water heater ......
Exhaust-steam piping where fuel could be conserved by covering..
Feed lines ....

(g) ENGINE-ROOM AND HEATING SYSTEMS: Value of question, 15. Mark received..........

Question 1. Is exhaust steam used: Entirely...... partly......not used?......

Question 2. State service for which this steam is employed: Heating......Cooking..... Dry room......Tank heating......Low-pressure turbines...... Other purposes ....

Question 3. Is there an excess of exhaust over requirements?

	Day	Night
Winter	....	..
Summer....	......	....

Question 4. Is there any low-pressure live steam used in the plant?......At what pressure? ....lb. gage. For what purpose?...... Heating...... Cooking......Dry room ...... Tank heating...... Other purposes.......

(h) SUPERVISION: Value of question, 10. Mark received ....

Question 1. Has the owner detailed a competent employee to supervise the work of fuel conservation in the boiler and engine plants with directions to report weekly on measures for economy and progress in conservation of fuel? Name and title of this employee

....
....
....

Question 2. Has the owner appointed a man in charge of the work of fuel conservation outside of the boiler and engine rooms described under Recommendations? Name and title of this employee

....
....
....

Let's "Can" the Bellyache*

This country—your country, our country—is at war. Let's cut out the bellyache.

We are at war with a powerful, relentless foe—a foe lusting for dominion. We are at war to save our own "hide"—our own individual hides.

By "making the world safe for democracy," we are making it "a decent place to live in"—for you and yours and me and mine. We are at war to perpetuate those things that stand for *our own* daily happiness. Let's not forget that. We're in this thing in self-defense. So, let's "can" the bellyache.

There are a few people who think this war isn't worth while, and most of them are keeping their mouths discreetly shut. But there are a host of flyspeckers, calamity howlers, and woe-betiders that are barnacles on the Ship of State. At heart most of them are loyal, good American citizens, but their tongues are loose. If you think this war is worth while, then join a movement to stop the mouths of those sobbers. Let's "can" the bellyache.

Our sympathy goes out to the man whose business has been hit a hard wallop by this war. We are sorry for the man who can't get cars; can't borrow money; can't ship goods, or can't make 'em. We are sincerely sorry to see a man suffer, even when his suffering may be necessary to further the chief business in which we are all engaged—the business of winning the war.

Let's "can" the bellyache.

If our public servants are sometimes wrong; if they misjudge conditions, men, measures, then those who suffer unjustly—while the nation trains off its fat and girds itself for war—let those with a common grievance get together, do some constructive thinking and planning and show our public servants, not with sobs and whines, but constructively, how things should be done. Let's cut out the fault-finding. "Can" the bellyache.

There are four things worth having in mind all the time:

1. The seriousness of the war—the necessity that it be prosecuted as the chief activity of the nation, at the cost of individual needs and preferences.
2. The fallibility of all men and, therefore, all public servants; the unescapable fact that no man or body of men could run even a *little* war and please everybody—and this war is the biggest war the world has ever seen.
3. The fact that our Government recognizes the necessity that business proceed so that the difference between income and outgo shall be as great as possible on the credit side—so that there may be profits and savings out of which to pay for the war.
4. The fact that in times like these the individual is of small consequence; the private need or preference is swallowed up in the public necessity—to the end that private needs and preferences and individual freedom may *eventually* survive.

We give up individualism to the end that we shall ultimately retain it. We shall not dare to clutch at our private wants or they must be torn from us. We give them up so that we may gratify them tomorrow.

We grasp the hand of the man whose business goes to ballyhack—we are sorry. But this is war. It is inevitable that the activities of peace shall be disarranged. Let us all help by silence and reproach to "can" the bellyache.

Let's organize, as we must, to criticize constructively; do the best we can, but mostly let's drive the dam machine of war until our enemies have had enough. Let's "can" the bellyache; stop the footless chatter of the street, the cheap mouthings of the malcontents. *We* are not overrun by the Hun. *Our* country is not devastated. Its people are not outraged nor its homes made desolate. The only sobs our country has an ear for are the sobs of those whose *hearts* are torn, those who have seen the war come to *their* homes, to demand the supreme sacrifice.

---

*An editorial written by Harvey Whipple and printed in "Concrete," Detroit, Mich., May, 1918.

Providing Ample Clearance Space

By M. A. Saller

A very important factor in the satisfactory operation of power-plant equipment, and one frequently overlooked by the designing engineer, is the matter of providing sufficient space around the equipment to permit the replacement of worn parts. Every operating engineer at some time has been confronted with the necessity of knocking a hole in the wall in order to remove the tubes from a boiler, or has had to move some auxiliary apparatus or piping in order to obtain sufficient clearance to remove and replace tubes in a condenser. Another common mistake is to so locate motors or engines that when occasion arises, for changing the pulley even, it is necessary to remove the machine from the foundation to secure the necessary clearance space.

PROVIDING SPACE TO MAKE REPAIRS

An easy way to minimize trouble from this source would be for the manufacturer to place on all standard drawings a notation as to the clearance space that should be provided about a machine or outline the space graphically on the drawing. Being thus noted, the point would receive attention by the designing engineer who would probably avoid the common error. This is done by a few manufacturers whose example could be followed to advantage by all.

Editorials

For the Duration of the War

ONE of the most striking things in a war replete with amazing happenings has been the remarkable adaptability displayed by the peoples of all nations. Under the pressure of great necessity and the urge of patriotic impulse they have voluntarily subjected themselves to conditions that before the war were undreamed.

In our own country, where the individual has been accorded freedom of action and opportunity such as no other nation can boast, we have imposed rules, regulations and restrictions that often savor of autocracy rather than democracy. But though in so doing we have shattered scores of precedents, our people have responded instantly and whole-heartedly to every change, convinced that no demand is too unreasonable to be met if it promotes the one great task of the present moment—the winning of the war.

In the name of efficiency and conservation we have turned over the railroads to the management of the Government, arbitrarily restricted the use of certain coals to certain prescribed localities, fixed the prices of fuel and food products, conferred upon the President the power to commandeer any public or private resource for the use of the nation in the conflict, set a guard armed with blue-pencils at the doors of the public press and in a hundred other ways limited and proscribed the operations of public and private enterprises.

Only the absolute need for coördinated effort and the wisest use of our resources could have brought about so radical a change in our methods of conducting affairs, and there are many who believe that when the pressure of necessity is removed, there will be a general reversion to pre-war conditions and modes of doing business.

Piffle and poppycock! Likewise fudge and fiddlesticks! The human race is not a crab. It does not progress backward. The war has thrown the spotlight, as nothing else could have done so effectively, on our criminal wastefulness and our unnecessary duplication of effort. We have realized that we have been working largely at cross-purposes, spending energy lavishly and to no good purpose. No reasonable person will deliberately return to a practice that he has found to be inefficient or contrary to the public welfare.

If the war has forced us to adopt plans that have resulted in better service at decreased cost, with smaller drains upon material and labor, there is going to be no retracing of steps when the war is over. Whatever has been found to be productive of the greatest good for the greatest number will be retained as a part of our system. Any individual or group of individuals who for selfish purposes would attempt to restore obsolete and slipshod methods must be regarded as an enemy of the public. If this war is accomplishing anything at all, it is teaching the gospel of teamwork and wiping out the heresy of self-interest.

Once they have proved their value and have been properly appreciated, economic policies will become a part of the habits of thought and action of the people. "For the duration of the war" is a refrain sung by selfish interests to revive their hopes and reinforce their courage. It is like the quavering whistle of the small boy who passes a cemetery at dead of night.

Celebrate Flag Day

IN 1775, two years before the Stars and Stripes came into use as our National Flag, George Washington wrote, "Please fix on some flag by which our vessels may know each other." Two years later, June 14, 1777, Congress met in Old Independence Hall in Philadelphia and adopted the following resolution:

> Resolved, that the flag of the thirteen United States be thirteen stripes, alternate red and white; that the union be thirteen stars, white in a blue field, representing a new constellation. The stars to be arranged in a circle.

Since that time the number of stars has been increased as the number of states has increased, until today there are 48. June 14 has come to be known as the Flag's Birthday, and it is this date that we celebrate as Flag Day.

We have thrown this country open to millions of emigrants from practically every nation of the world, to come and live within our borders, saying this is a land of freedom and equal opportunity, without teaching the meaning of these terms. For years we have gone along in our peace-loving, idealistic way without giving very serious consideration to what the Stars and Stripes really mean to us, what a precious thing this liberty is, which we have held up as symbolical of our national attitude. Too long have we been doing this, therefore is it no wonder that many whom we have invited to our shores have been inclined to take the duties of citizenship here lightly and in many cases have entirely neglected to assume these responsibilities.

Flag Day offers to every employer in this country the opportunity to bring home to his foreign-born employees what it means to be an American; how that the Stars and Stripes have greater significance to them than ever before, since for the first time in our history men of all nations who have adopted America as their country are fighting under the American Flag on the great battlefronts of France to make the world a safe place for freedom, right and equal opportunity, to enjoy which they came to our shores. There are thousands of foreign-born workers in our industries that have those near and dear to them in our military and naval forces, who would welcome the opportunity to join with the American-born to pledge their loyalty to the Flag and to the great cause we are fighting for, and it is the patriotic duty of every employer in this country to see to it that his employees have the opportunity on June 14 to get together for a flag raising.

This is a timely occasion for the employer to get the idea across to his employees that they are working for their country and for the boys at the front. This idea, when once instilled, will make strikes, sabotage and restricted output a thing of the past and develop a loyal spirit among native- and foreign-born employees by making them realize that America is the land of the square deal and equal opportunity.

The employer, in addition to producing the materials essential to winning the war, must also help develop a new American spirit. This was very eloquently expressed recently by Secretary of the Interior Franklin K. Lane, in an address before an educational conference in Washington, D. C.

> And we who are not permitted to fight, what shall be our part? Let it be our resolution that when our sons return they shall find a new spirit in America, a deeper insight into the problems of a striving people, a stronger, firmer, more positive and purposeful sense of nationality. We shall make America better worth while to Americans and of higher service to the world.

Flag Day offers an opportunity to help make this resolution a reality.

Cent-a-Gallon Gasoline a Dream

WHILE we are waiting for the report of the five internationally known scientists, who we understand have been appointed by Garabed T. K. Giragossian and approved by the Secretary of the Interior, to investigate the former's sources of free energy and learn whether the said Giragossian is to be a great benefactor to humanity or whether his claims are just plain buncombe, the story of the doings of Louis Enricht, of Farmingdale, L. I., and his "Cent-a-Gallon Gasoline," published in the New York *Tribune*, May 5, an abstract of which appears on page 854 of this issue, will help in provide fuel for our speculative imaginations.

Gasoline at one cent per gallon, if such a thing were possible, would seem to be about the equivalent to tapping the inexhaustible reservoir of energy in the atmosphere. However, as far as we know, the T. K. Giragossian free-energy motor, or "Garabed," as he calls it, exists only in the would-be inventor's imagination, while Louis Enricht has managed to put his mysterious something across in such a way as to interest Henry Ford, B. F. Yoakum and, according to his own statements, the governments of two or three countries, without revealing his method of doing it.

No doubt many of our readers have speculated upon what would be the results if all this was a reality and not a dream or a hoax; how some day all the millions invested in pipe lines, oil-refining and oil-pumping equipment would cease to earn dividends; how gasoline, which is becoming one of the most expensive and essential fuels, would some day be one of the cheapest and most commonplace; how the fortunes of the millionaires of the oil industry would fade away—but you need not speculate any longer, for, according to Louis Enricht's own words, he has had to abandon the idea of his "Cent-a-Gallon Gasoline," and, on account of the great increase in the cost of chemicals during the last two years, his mysterious motor fuel will now cost the public "twelve cents per gallon." When it comes to war profiteering, Louis Enricht appears to be a joy rider.

However, this would-be "green-fluid wizard" seems to be a sort of a generous creature after all, for according to his own statements he has had a conference with Secretary Baker and Attorney General Gregory, and this Government wants his secret for war use only, while he wants the Government to protect him after the war and license him to manufacture his compound and make it illegal for anyone else to produce it. On this plan he will sell his fuel to the Government at ten cents a gallon, and the extra two cents charged the public he is willing to pay the Government as a tax. This, according to his estimate, would enrich the Government by seventy million dollars per year, which is equivalent to a two-cent tax on three and a half billion gallons. Louis must expect to do some business when he gets started, since the total gasoline production in the United States in 1917 was only about two and a half billion gallons.

Like Giragossian, Enricht has always held up the difficulty of protecting his idea as a reason for not revealing his secret, if he has one; and by this subterfuge he has managed to cover himself at every turn from his first public demonstrations in 1916 to what he claims to be his latest offer for his fuel from the Government.

Now that "Cent-a-Gallon Gasoline" has increased to twelve cents in the last two years, it should be enough to convince the trusting public that whatever Enricht may have is a hoax, and that it is only one more of the something-for-nothing schemes breathing its last and about to pass into oblivion. Is it not about time that at least those who are supposed to be familiar with the laws of physics, chemistry and engineering cease to lend their attention to schemes that are so far removed from all laws of reason?

Soot-Blower Data Solicited

ON OTHER pages of this issue is an article dealing with mechanical soot blowers, giving experience from a number of plants as to the saving effected in coal and labor and the character of the service rendered. As far as they go the various reports are favorable, but for the most part they lack definite data to back up the assertions made. Those published are only a few of the responses received. The others merely state that no data on the subject are available.

A loss that may account for two to eight per cent. of the fuel is surely worth analyzing. It would be interesting to know the amount of steam required to blow different sizes and types of boilers, the relative efficiencies of mechanical and hand cleaning and the cost of maintenance in various plants. With these points in view it should not be difficult to obtain data sufficiently accurate for the purpose in hand. We would welcome other contributions to the subject. A general knowledge that a thing is good is not sufficient. Those interested in a device of this character should know how good and at what expense.

There are few engineers and technical men who do not view the move to abolish the study of German language in the schools as a piece of downright foolishness.

Correspondence

Texas Also Needs a License Law

The account in the issue of Apr. 2, pages 463-4, of a boiler explosion in a laundry at Providence, R. I., resulting in the death of three men, and the editorial comment, "Does Rhode Island Need a License Law?" recall an incident that I observed a few years ago in this state.

I stopped overnight in a small town in central Texas and next morning before train time, I decided to walk around and see some of the plants. The first one I came to was a small laundry. The boiler room opened on the sidewalk, so I stepped in to have a chat with the engineer, but there was no one in sight. The boiler was of the horizontal-tubular type, about 35 hp., and judging from its general appearance, it was of a "very indefinite age." The steam gage registered 85 lb., and glancing at the water column, I saw that there was no water in the glass. I had a feeling that as an engineer it was my duty to "stick around." While I was looking the outfit over a boy came into the boiler room from the laundry, and I asked for the engineer.

He said, "Why, the boss generally looks after the engine, but he's gone up town and told me to 'sorter' look out for her until he got back." "Well," I said, "someone had better be 'looking out for her' pretty soon, as your boiler don't seem to have any too much water in it." He blew the column and only dry steam came out. He became very much excited and asked what I thought he had better do. I looked in the furnace and saw that he had very little fire (lignite was being used as fuel) but plenty of ashes. So I told him I thought the best thing to do would be to cover his fire with a few shovels of wet ashes, let the steam drop back, shut everything down and wait for the boss.

I left him shoveling ashes on the fire and have often wondered what the boss had to say when he finished his "political argument" up at the post office and returned to "generally look after" the boiler. This is only one of many instances where the boss "generally looks after the boiler" in small isolated plants, and it shows that Texas as well as Rhode Island needs an engineer's license law. S. F. FARLEY.

Galveston, Tex.

Greater Efficiency in Internal Combustion

Your editorial in the issue of April 16 on "Internal-Combustion Economy" is timely and I trust will bring out some comparative efficiencies between engines of this type working under the average and best conditions. While a hot cylinder wall is conducive to a minimum jacket loss, the greatest field for improving thermal efficiency is found in expanding the working charge to a greater degree.

The power stroke is now of shorter duration than the compression stroke, but if the working stroke were prolonged until the terminal pressure approached the initial pressure of compression, a larger amount of heat would be converted into work before release. The indicated work with such expansion is from 23 to 26 per cent. greater for the same amount of fuel, but like a single-cylinder steam engine, there is a limit to the terminal pressure, as nothing is gained by expanding steam lower than 18 to 19 lb. absolute because the mean effective pressure of further expansion is less than that required to overcome the mechanical friction of the moving parts; so in an internal-combustion engine, ordinarily twice as heavy per unit of output, it has been found that there is a net increase in fuel consumption with expansion before release to about 23 lb. absolute. The pressure of release at full load is usually 25 to 30 lb. absolute, or above the pressure of initial compression, and the temperature is about 1500 deg. F., while an expansion reducing this pressure to 23 lb. absolute will reduce the temperature of release about 1000 deg. and will increase the total efficiency 12 to 16 per cent.

Of course, an engine with a long stroke has more friction than one with less piston displacement, but a compound noncondensing steam engine has in many cases double the friction of a simple engine of the same output, yet the saving in cylinder condensation exceeds the frictional losses, and noncondensing compound steam engines are commercially successful.

If there were no cylinder condensation of the working medium in a steam engine, the same number of expansions in a single cylinder would show a greater efficiency than when carried out in two or more cylinders. It is the writer's opinion that in its ultimate development the internal-combustion engine will have a working stroke of longer duration than the compression or induction stroke. C. E. SARGENT.

Indianapolis, Ind.

Excessive Compression Lifted Valve

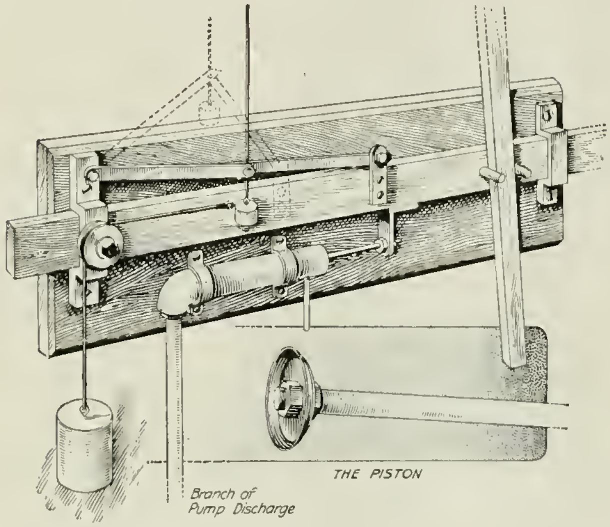
We had a distressing experience for a couple of days after putting a new piston rod in a 20 by 32-in. mill engine. Whenever the throttle was closed, there would be a terrible clattering racket set up inside of the valve chest, continuing as long as the engine was in motion. If, however, some steam was allowed to enter while the engine was slowing down, the noise was not nearly so bad.

The cause was found to be that the new rod was slightly longer than the old one, so that the piston traveled up close to the head end, causing enough compression to lift the balanced slide valve off its seat, but as soon as the valve lifted, the pressure was released and the springs slammed the valve back against the seat.

New York City. J. LEWIS.

Automatic Control for Belt-Driven Pump

A plant of which I once had charge used large quantities of water pumped from a well into an overhead tank to be heated. The duplex belt-driven power pump with hand control proved unsatisfactory as the tank was often either empty or overflowing and wasting hot water, and to overcome this difficulty I made the control automatic by the following means: I extended the belt shifter along the wall back of the pump with two supports for it to slide in. The pump discharge line had a balanced valve, operated by a float in the tank, so that when the tank was full this valve closed and of course the pressure would build up in the pipe line. I connected a branch to this line and led it back of the pump to where the shifter was and connected to it a cylinder made of 1½-in. brass pipe. The piston rod was made of ½-in. iron rod with a cup leather washer on the end to fit into the cylinder; the other end was connected to the belt shifter, which was counterweighted, as shown in the illustration.



BELT SHIFTED BY HYDRAULIC PRESSURE

When the tank filled and the valve closed, the extra pressure would force the piston and rod outward and shift the belt to the loose pulley, stopping the pump. When the float valve opened and the pressure was released, the belt was thrown on the tight pulley by the counterweight. This arrangement was an improvement over hand control, but it was too sensitive, for the pump would start too often, sometimes making less than one revolution before stopping again. To overcome this, I arranged a jointed brace, as shown, so that when the shifter moved to the off position, the jointed part would drop a little past a straight line, "toggle locking" the shipper until the toggle was tripped again. This was done by a second float in the tank, connected to the toggle and a small weight by a wire. When the water level dropped eight or ten inches the float would trip the toggle, allowing the pump to start and fill the tank, after which it would stop and be locked in the off position again. The pump starts and stops pretty often, but it receives no attention for months at a time beyond an occasional oiling.

New Bedford, Mass. H. K. Wilson.

Removing Piston-Rod Packing

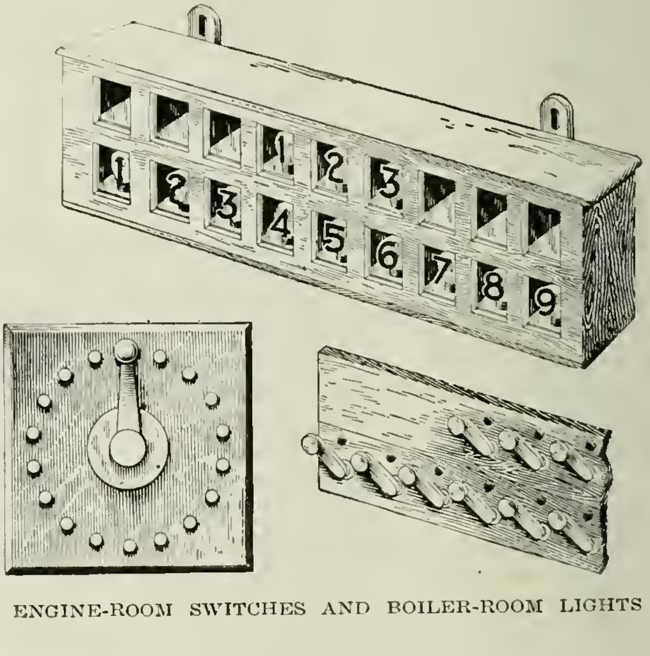
I have a way of my own of removing packing from piston rods of engines, which may be new to some engineers. Place the engine on the center toward the cylinder, remove the nuts which hold the gland in the stuffing-box, open the cylinder cock at the head end and close the one at the crank end, then give the engine a quick turn of about half a revolution and the air compressed in the cylinder will blow the packing out.

This of course applies only to engines that are smal' enough to be turned over by hand, but it is preferable to blowing the packing out with steam, as it leaves the cylinder cool to repack and there is no danger of breaking the gland as when using steam. Care must be taken, however, not to let the engine turn a complete revolution or the gland may be jammed or broken.

Binghamton, N. Y. Edward J. Dowd.

Fireroom Load Telegraph

It is convenient for the firemen to know what load is being carried in the engine room, but sometimes rather inconvenient to keep them informed. Various devices are employed for this purpose. The one shown was used in a power plant where I once worked. A box with numbers from 1 to 3 and 1 to 9 painted on its glass front, with a small lamp back of each number, was placed in plain view of the firemen in the boiler room, and a bank of twelve single-pole switches, each one corresponding to a number on the board in the boiler room, was placed handy to the engine-room operator, the upper row to show the load in thousands and the lower row, in hundreds. As the switches were turned on, the corresponding lamps lit up, informing the firemen of the load carried.



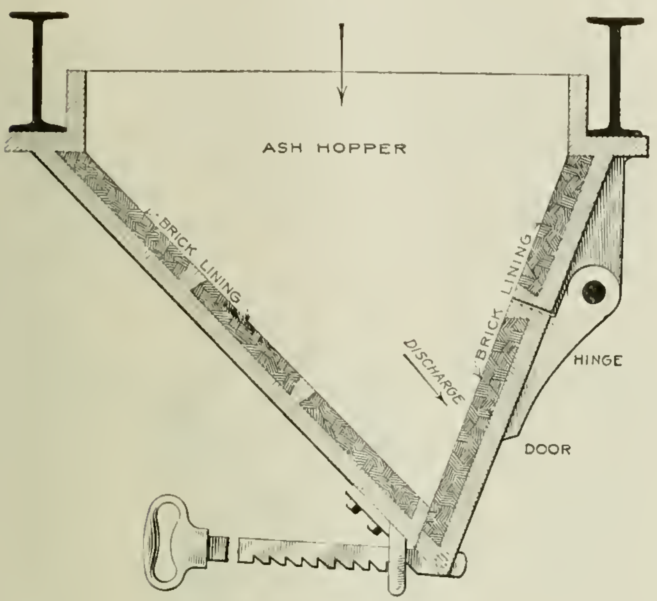
ENGINE-ROOM SWITCHES AND BOILER-ROOM LIGHTS

A handy bank of switches may be made out of an old rheostat with a lamp connected to each contact button and to a common return wire at the lamp bank. There are enough contact points so that the numbers can progress all the way by hundreds. D. R. Hibbs.

New York City.

Brick-Lined Ash Hopper

In some automatic stokers the ashes from the fire fall into a receiver or hopper below. These ashes may be left in the hopper two or three hours before being removed and carted away. The hopper is made of cast-iron plates which, if not insulated, come in direct contact with the hot ashes and become warped and are soon put out of commission. The illustration shows an ash hopper fitted with a firebrick lining built according to the writer's own ideas and used in a local plant.



BRICK-LINED ASH HOPPER

Induced-Draft Fan Puzzle

I once had an interesting experience in connection with an induced-draft fan placed on the roof of a large hotel and used in connection with two marine-type boilers. The construction of the building prevented placing the fan near the base of the stack, and the only available space was on the roof within 20 ft. of the top of the stack; the flue had a great many crooks and turns and was divided into two parts, one from the boilers and the other evidently a ventilating flue.

When tested, it was found that there was no apparent increase in draft over the fires, and the fan was taking considerably more power than was originally figured on. The temperature readings at the boilers and at the fan inlet showed a large drop, which would seem to indicate that the fan was handling a lot of cold air from somewhere. This was puzzling, but it was decided that the flue had a great many small leaks.

In order to determine if there were any large openings between the stack and ventilating flue, a newspaper was torn into small pieces and thrown into the ventilating flue while the fan was running. A few seconds after they went in they came flying out from the outlet of the fan, proving in a very striking manner that there was a hole somewhere in the stack and that the fan was drawing air through it and consequently handling nearly all cold air. This, of course, accounted also for the wide difference in temperature and for the fan taking an excessive amount of power. A hole 12 in. in diameter was found about one-third the way up the stack. Before its discovery the owner of the building was positive there was no hole in the stack, so to square himself the check in payment for the installation was sent at once.

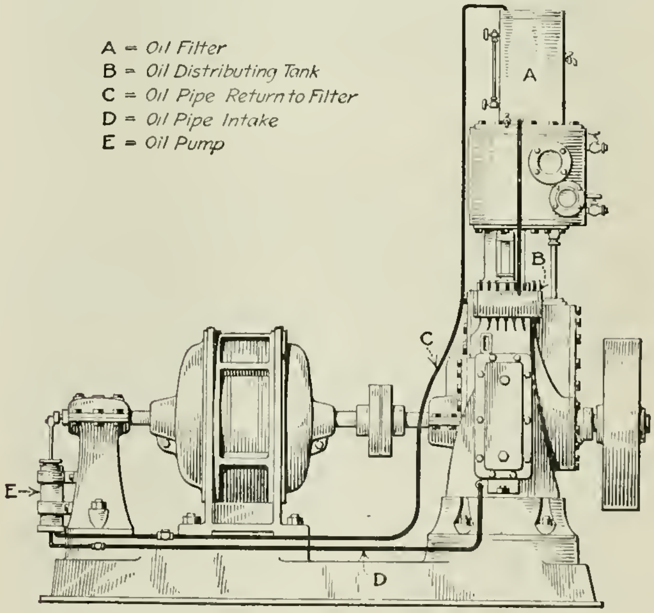
G. C. Derry.

New York City.

Engine-Oiling System

The illustration shows the general plan of an automatic engine-oiling system of the "home-grown variety" somewhat on the order of the one described by Mr. Morrison on page 60 in the issue of Jan. 8, 1918. Oil from the crank case was originally discharged into a pail, but by the new arrangement the pipe was extended to the end of the bedplate supporting the outboard pedestal bearing, and connected to a home-made pump, from which the oil is discharged to a reservoir and filter located above the engine and drains by gravity to the regular distributing tank on the engine. All of which is "according to Hoyle," but the construction of the pump might be described as something "fearful and wonderful, to wit:

The pump body was a nondescript piece of brass threaded inside at one end for a stuffing-box and outside at the other end for the oil-pipe connections. A 1-in. drill was run through from end to end, forming a working barrel. The piston, piston rod and pump head were originally the stem, disk-holder and bonnet of a bath cock fitted to the size and thread of their respective new mates. Motion is imparted from a 7/8-in. capscrew tapped into the shaft center with a steel pin located 3/8-in. off center, making a 3/4-in. stroke crank. The pump body is attached to a cast-iron plate with U-bolts, and that in turn is fastened to the outboard bearing pedestal with studs.



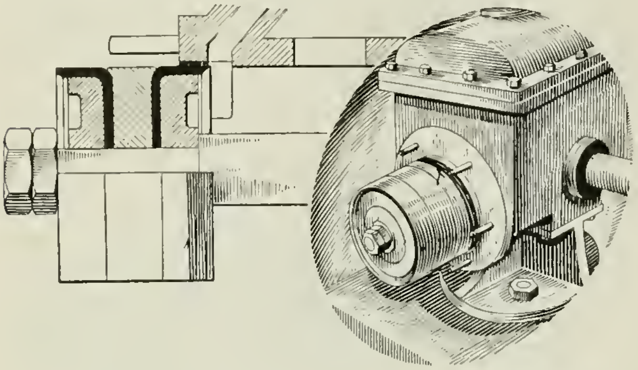
AUTOMATIC OIL FILTER AND RETURN SYSTEM

The description may read like that of the remains of a steam calliope, but the pump does the work just as well as one bought for the purpose and the "automatic oiling system" saves a lot of time and attention.

Ray Brook, N. Y. J. J. Brewer

Entering Leather Pump Cups

We had considerable difficulty replacing the plunger in a Davidson pump, with a set of new leathers on it. Using sheet iron proved of no avail, but we finally succeeded in the following manner: The edges of the cups were very tightly wound with strong thread and smeared with grease. The plunger then entered easily. Of course after a few strokes the thread was worn off, leaving the cup "lips" to serve their proper function.



STRONG THREAD WRAPPED ON LIP OF LEATHER CUP

Another good stunt pulled off lately was as follows: We have only one brine pump, and when one of the round notched packing gland nuts on a steam piston rod broke one day, it meant shutting down the entire refrigerating system unless it was repaired promptly. The engineer on watch found that a 2½ x 1¼-in. reducing sleeve would take the place of the packing nut, so he put it on and had the plant running again in an hour. R. J. DALTON.

Woodhaven, L. I.

Water-Heating System

In a silk mill where there was a heavy demand for hot water for boiling the silk, they used to draw cold water into the tubs and bring it to a boiling temperature with live steam through a "full-open" 1¼-in. pipe. To boil 250 gal. it took 15 to 20 minutes. With ten tubs in operation there was a noticeable extra demand on the boilers and the coal pile. After considerable argument I was allowed to put in the following equipment.

The boiler room had a monitor extending along the middle of the roof, below which ran the exhaust pipe of the main engine. In this I built a 1200-gal. tank and put in a closed feed-water heater with 6-in. steam connections and connected the water side to a centrifugal pump with 1½-in. connections from the bottom of the tank to the pump, then to the bottom of the heater. From the top of the heater another pipe discharged into the tank to circulate the water from the tank through the heater and back to the tank. With the centrifugal circulating pump in operation the water was soon heated and kept at from 150 to 212 deg. F.

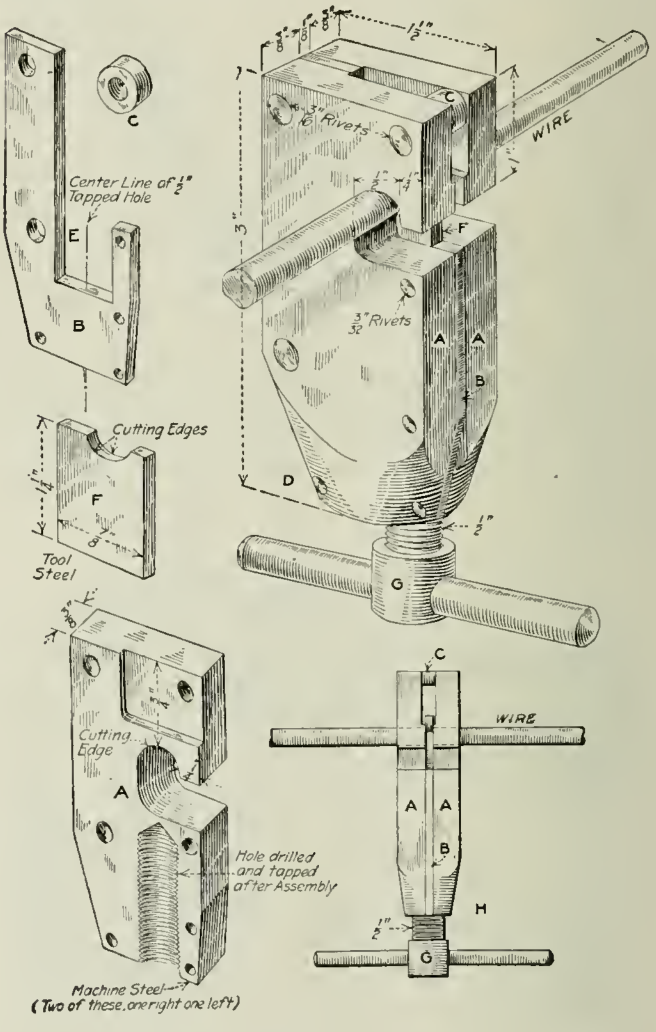
In this room there were two driers, one having 5600 ft. and the other 2800 ft. of 1¼-in. pipe operating under boiler pressure (70 lb.). These were trapped and the discharge led into the hot-water tank, thus saving both heat and water. Water was supplied to the tank by means of a balanced float valve. After this system was placed in operation, it was a common thing to see a tub of water boiled in two minutes, and the saving in coal amounted to about a ton a day, which is pretty good interest on a $600 investment. H. K. WILSON.

New Bedford, Mass

Screw-Type Wire Cutter

A handy tool for cutting heavy copper wire up to 0.5 in. diameter is shown in the figure. The body of the device is made in four parts and assembled. Two pieces, one right and the other left, are made similar to that shown at *A*, and two other pieces *B* and *C*. The parts are assembled and riveted together as indicated at *D*, after which a ½-in. tap hole is drilled and tapped so that it will pass through the center of the recess *E* in part *B*. The holes should extend well down through parts *A*, as indicated in the figure. The recess *E* in part *B* forms a pocket for the cutter *F* when the tool is assembled. In operation the screw *G* is turned back and cutter *F* dropped into the pocket, thus allowing the wire to be placed in the tool, as shown at *D*. The screw is now turned and the cutter shears the wire between the cutting sides of the shoulders *A*, as indicated at *H*. The parts are made of tool steel and hardened on the cutting edges. This little implement can easily be carried around in the tool kit. M. P. BERTRANDE.

Ozone Park, N. Y.



PARTS AND ASSEMBLY OF CUTTING TOOL

Inquiries of General Interest

Relative Loss of Draft in Square and in Round Flues—What is the relative loss in force of draft in square and in circular smoke flues? S. R.

The draft-retarding effect of a square flue is about 12 per cent. greater than of a circular one of the same cross-sectional area.

Charles' Law of Gases—What is Charles' law of the expansion of gases? C. R. D.

The law of Charles, sometimes attributed to Gay Lussac, asserts that all gases have the same coefficient of expansion, and this coefficient is the same whatever the pressure supported by the gas. Hence, for each degree of rise or fall of temperature at constant pressure, its volume will be increased or diminished by a fixed fraction of its original volume. This fraction has been computed to be $\frac{1}{493} = 0.0020284$ on the Fahrenheit scale, the temperature of the original volume being that of melting ice.

Heat Lost in Chimney Gases—What percentage of heat in coal is lost in boiler chimney gases? W. N. R.

The loss depends on the quality, quantity and temperature of the gases. In ordinary boiler practice with natural draft it is customary to supply about 100 per cent. excess of air in order to insure complete combustion. With complete combustion of coal and such excess of air, the losses with different temperatures of chimney gases are about 17.5 per cent. for 400 deg. F.; 21 per cent. for 500 deg. F.; 25 per cent. for 600 deg. F.; 29 per cent. for 700 deg. F.; and 33 per cent. for 800 deg. F.

Chattering of Pressure-Reducing Valve—What can be done to stop chattering and hammering of a pressure regulator used on the steam supply to a steam pump near the steam chest? F. L.

Locate the regulator far enough from the pump so that the volume of steam contained in the pipe between the regulator and the steam chest provides a cushion for the action of the valve without sudden changes of the discharge pressure. This usually will be attained by placing the valve at a sufficient distance from the steam pump to obtain a volume of supply pipe equal to the volume of the steam cylinder of the pump.

Laying Up Heating Boiler—Should a return-tubular boiler that is used for heating be laid up filled or emptied of water? R. L. D.

The boiler should be emptied and after being thoroughly cleaned and dried should be closed up tight. Leaving a boiler stand entirely filled with water during the summer months will prevent rapid rusting at the ordinary water line, but will cause the exterior of the shell and the interior of the fire tubes to rust more rapidly from condensation of moisture out of the atmosphere. Whether the boiler is left filled or dry, the smoke uptake should be disconnected and sealed and furnace, ashpit and all cleaning doors closed tight, to prevent external rusting from circulation of air over the heating surfaces.

Clinker Trouble—Our present coal contains considerable slack and clinkers badly. What is suggested to prevent the trouble? W. B. G.

Keep the fuel bed only about 5 in. thick and fire small charges at frequent intervals. Promptly cover the brighest spots with fresh fuel to prevent holes from burning out that will allow coal to drop through to the ashpit. Avoid excessive stirring of the fire. Any working of the fire bed that may be necessary should be done from the bottom. Keep the bed level by stoking. Leveling the fuel bed with a rake or other firing tool is likely to cause clinker by lifting the ash to the fuel bed. Keep ashpit doors open and regulate the draft with the uptake or stack damper. Promptly quench any ashes or coal falling through the grates. If ashpit is water-tight, keep water standing in it. If that is impractical, blow steam under the grate. The exhaust of a pump or any other supply of waste steam will be beneficial.

Testing Steam Consumption of Engine—How is the steam consumption of an engine determined? W. G. R.

The steam consumption while driving a stated load can be determined by a steam meter that has been calibrated for the conditions, but more generally such tests are made by actually weighing the feed water used for generating the steam supplied or by condensing the exhaust and weighing the condensate. For condensing the exhaust, an ordinary surface condenser may be used, or a series of closed feed-water heaters may be connected together for obtaining sufficint condensing surface. Measurement of the condensate is usually to be preferred to feed-water measurement as less likely to introduce errors from irregularity of working conditions, leakage or use of steam for other purposes than for supplying the engine under test. For establishing uniformity of conditions and reducing the percentage of errors, a feed-water test should have a duration of at least five hours, but with the condenser method an hour's test is sufficient after the normal working conditions have been established.

Quality of Steam Shown by Calorimeter Test—What is the quality of steam determined by a throttling calorimeter test from the following data: Pressure of steam in the pipe from which the sample is taken, 120 lb. gage; temperature in calorimeter, as indicated by the thermometer in the well, 241 deg. F.; pressure in calorimeter as indicated by the manometer, 3½ in. of mercury; barometer 28 in.? R. G. C.

With a barometer reading of 28 in. the pressure of the atmosphere was $28 \times 0.491 = 13.75$ lb. per sq.in. and the absolute pressure of the steam was $120 + 13.75 = 133.75$, or about 134 lb. per sq.in. absolute; and with a pressure in the calorimeter of 3½ in. of mercury, or $3\frac{1}{2} \times 0.491 = 1.72$ lb. per sq.in. above the pressure of the atmosphere, the absolute pressure in the calorimeter was $1.72 + 13.75 = 15.47$, or about 16 lb. absolute. The heat of one pound of steam in the pipe would be equal to the heat of 1 lb. of the steam in the calorimeter.

In one pound of the steam in the pipe at the pressure of 134 lb. absolute, if

h = The heat of the liquid,
q = The quality or fraction of dryness,
L = The latent heat, then the heat of 1 lb. of the original steam would be $h + qL$, and if
H = The total heat in 1 lb. of saturated steam at the pressure which existed in the calorimeter,
T = Temperature of the superheated steam in the calorimeter as indicated by the thermometer.
0.48 = The specific heat of superheated steam at the pressure in the calorimeter,
t = The temperature of saturated steam at the pressure which existed in the calorimeter,

then the heat in the calorimeter $= H + 0.48\ (T - t)$, and

$$h + qL = H + 0.48\ (T - t), \text{ or}$$

$$q = \frac{H + 0.48(T - t) - h}{L}$$

From observations and the steam table, $H = 1152$ B.t.u.; $T = 241$ deg. F.; $t = 216.3$ deg. F.; $h = 321.1$ B.t.u.; and $L = 870.4$ B.t.u. and by substituting,

$$q = \frac{1152 + 0.48(241 - 216.3) - 321.1}{870.4} = 0.968 = 96.8 \textit{ per cent.}$$

[Correspondents sending in inquiries should sign their communications with full names and post office addresses. This is necessary to guarantee the good faith of the communications and for the inquiries to receive attention.—Editor.]

Annual Meeting Boston Section, A.S.M.E.

The importance of fuel conservation and the remarkable progress in the production of ships in the United States were featured at the annual meeting of the Boston section of the American Society of Mechanical Engineers, held at the Engineers' Club, Boston, Mass., on the evening of May 29. Chairman Albert C. Ashton presided, and the principal speakers were Dr. Ira N. Hollis, past president, and President Charles T. Main, of the national society, and Dr. Charles A. Eaton, of the United States Shipping Board. The meeting marked the climax of one of the best engineering-society seasons ever enjoyed in the New England metropolis. The sessions of the Boston section have been keyed to a high patriotic note; some of the most distinguished officers in the field service of our Allies have addressed it, and the attendance and discussions have reflected a general desire among the members to be of the utmost possible service to the country in this critical period.

Doctor Hollis' Address

Dr. Hollis, who is chairman of the recently appointed Fuel Conservation Committee in Massachusetts, under New England Fuel Administrator James J. Storrow, was the first speaker. He referred briefly to the vital necessity of backing up our military and naval efforts by campaigning at home against every form of waste. America has wasted her natural resources for generations, and the time has come to call a halt. "The subject of conservation," he said, "has come to assume a certain religious aspect, and it is our sacred duty to preserve what the good God has given us, for the welfare of those who come after us no less than for present-day needs. It is the desire of every generation to lift the race a little higher than it found it. Democracy bids fair to fade away if we continue to waste our resources." Dr. Hollis pointed out that coal saving, important as it is, is not the whole end and aim of conservation; the soil, the forests and other resources must be maintained for the general welfare. The speaker said that we must all learn to work together as good neighbors and friends. In closing, he cited an example of teamplay from the battle of Santiago. The firemen on the battleship "Oregon" heard little and saw nothing of the sea fight, and during the long pursuit of the Spanish ships gradually became weary of their arduous tasks at the furnaces. Seeing this, the officer in charge of the fireroom sent a request up the speaking tube that the commander of the vessel authorize the firing of a 13-in. gun to hearten the force below decks. Captain Clark agreed, and presently a 13-in. shell went sailing through the air toward the enemy. Instantly there came a scraping of shovels on the floor and an Irish fireman who had become a bit weary in well doing seized a big shovelful and with a "Take that, you dirty Dago!" hurled home his charge. Such was the effect of a coöperative stimulus upon tired muscles and minds previously out of touch with the stirring events above decks. Every American must take a personal interest in helping the country at this time, the speaker declared, as he took his seat.

President Main on the Fuel Situation

President Main briefly outlined the serious fuel situation which New England is facing with respect to next winter's supply. The New England Fuel Administration estimates that 33,400,000 tons of coal will be needed in the year; the Federal Administration at Washington has reduced this estimate to 30,000,000 tons. There are not enough vessels available to carry the water-borne share of even the smaller amount mentioned. It is estimated that 386,000 tons of shipping would be required to transport the water-borne coal to New England, on the basis of 100 per cent. efficiency in trips and cargo loading and unloading. On Jan. 1, 1918, there were only 200,000 tons available, and a week ago, 276,000 tons. It is anticipated that 60,000 tons more of shipping facilities will be added this year, so that the total estimated tonnage available will be 336,000 tons. The necessity for saving fuel in New England is therefore extreme, and the problem is, How is the manufacturing to be done with the coal which the plants will receive? To answer this question an organized attempt is being made to bring home to the mind of every plant owner in the state the importance of fuel economy, and a booklet has been prepared by the New England Fuel Administration showing how this has been taken up by four representative plants through the organization of shop fuel and efficiency committees, with savings effected during the past winter, and the suggestion that other plants follow suit. Members of the Fuel Administration and engineers in private practice stand ready to assist plant owners in realizing the maximum benefits from their fuel. Extracts from the reports of four plants follow:

Crompton & Knowles Loom Works, Worcester, Mass.

As a result of various steps an economy of not less than 15 per cent. in the use of fuel has been effected. On account of the very unusual winter conditions it is impossible to ascertain the exact amount.

On taking up the matter at the beginning of the winter we appointed from our foremen and executives a so-called Shop Fuel Commission. A little later we appointed a Shop Fuel Administrator, whose business it was to follow up the various methods inaugurated, to see that the best results were accomplished therefrom, and also to see that continued interest was maintained.

The several points covered may be listed under four headings: Improvement in boiler-house practice; improvement in use of power; improvement in use of heat; improvement in use of lights.

Improvement in Boiler-House Practice

1. Raising temperature of feed water by return of condensation. We succeeded in raising the temperature of feed water entering the boilers from 180 deg. F. to 200 deg. F.
2. The burning of all wood scrap and shavings produced in the plant, amounting to five or six tons a day of this material.
3. The establishment of better boiler-room practice by putting observers in the boiler rooms day and night for several days and nights to determine rate and efficiency of firing. The usage of coal by half-hour periods, as fired, was recorded for many days and plotted, from which was evolved a better practice as to uniform and more economical firing.
4. The weighing of all coal supplied to the boiler room and only allowing a certain amount to be used in definite periods. The remainder of the coal was locked up, so that the fireman had to be economical in the use of the portion that was issued to him.
5. Installation of pinhole grates and under-grate blowers to allow use of screenings. While the screenings have not been very high grade, we have been able to conserve appreciably our soft-coal supply. We are analyzing our screenings and discontinuing the use of all that show an unusual percentage of dirt and ash.

Improvement in Use of Power

1. Under the direction of our Shop Fuel Commission, an inspector observed the number of idle machines on which belts had not been thrown off. Vigorous action resulted in the number of machines running idle and wasting power being reduced to an absolute minimum.
2. Where the load was not sufficient to get the maximum efficiency from a motor, conditions were changed to make this possible. All cases of motors working underloaded were eliminated.
3. All overtime that involved the inefficient operation of machinery was stopped.
4. The use of large elevators was restricted to actual needs.
5. Our entire requirements of power had been purchased from the Worcester Electric Light Co. up to last December, obliging us to use live steam for heating. Since the need of fuel conservation became critical we reduced the Worcester Electric Light Co.'s load, at their request, 40 per cent., by operating our own engines and using only exhaust steam for heating. This has been accomplished with practically no increase in the use of fuel.

Improvement in Use of Heat

1. Using only exhaust steam.
2. Under the Shop Fuel Commission a thorough inspec-

tion was made of all doors, windows, transoms, etc., throughout the plant. These were promptly fixed up, and every time the shop shuts down a designated committee goes around immediately after the shutdown and sees that all places are closed. This has saved considerable fuel.

3. On all doors that opened to the outside, automatic door closers were installed.

4. By the appointment of a special inspector we have been able to cut off every day from 20 to 50 per cent. of our heating surface. This has been done by listing the number of feet of heating pipe in the various departments and by having the inspector follow the sun, so to speak, in turning off the steam in the various departments, as the temperature rose in the morning. This saving has been very heavy, as it meant from 200,000 to 500,000 heating foot hours per day. We have upwards of twenty acres of floor space and about twenty miles of pipe for heating.

5. The covering of all exposed steam piping.

Improvement in the Use of Lights

The saving in fuel in connection with the use of lights was large and accomplished in three ways, particularly:

1. The development of interest on the part of the foremen in connection with the problem and actual inspection at various times of the day of lights used, which resulted in the cutting out of a large number of unnecessary lamps.
2. Carbon lamps are replaced with tungsten lights.
3. Reducing the wattage of lamps in places where heavy illumination seemed unnecessary.

Dennison Manufacturing Co., Framingham, Mass.

Study was made in the power house to increase the efficiency of the plant, and a considerable gain was made in the number of pounds of steam evaporated per pound of coal. Study of the power and lighting load was made, and a considerable improvement in conditions was brought about by the following changes made in the manufacturing departments:

Heating of the factory was put into the hands of men appointed in each section, who carried out instructions which were given by the Conservation Committee. A schedule of proper temperatures was posted in each room, and the results of their work was checked up from time to time.

Outside of working hours the watchman received specific instructions as to the proper temperature to be maintained, and steam was turned on in the various departments at specified times in the early morning hours.

Thermometers were installed all through the working departments for the purpose of observation, so that the heat in the department could be kept at the proper point without opening the windows or using more steam than was necessary.

Heating coils in bridges and isolated parts of the plant which were not sprinkled were discontinued, and the valve wheels removed so that they could only be turned on by authorized parties, in case of necessity. This applies to the garage and stable, stair tower, toilets, etc.

Steam was shut off the boarding house while rooms were vacant.

Office work was moved in some cases to warmer locations in rooms where it was not necessary to keep the high temperature, and protections were arranged around the desks so that these locations could be heated to a greater extent than the remaining parts of the room.

Any orders for steam in unusual places or outside of working hours had to have the approval of the man at the head of the department.

A study of the use of hot water was made in all departments, and where it was only used for convenience it was shut off. Self-closing faucets were installed in some cases and the number of outlets decreased was over 30 per cent. The use of hot water was discontinued in the main office as well as in the manufacturing departments.

A reduction in the general illumination around the plant was made; the amount of light used under the existing conditions was cut down to the minimum, and in some places discontinued. Lamps of lower candlepower were substituted in many cases for a larger sized lamp. The time when lights were turned on was curtailed. The sign lighting was discontinued and the street lighting and factory-yard lights were reduced to a minimum consistent with the safety of the plant and the prevention of accidents to employees.

The watchmen were instructed to see that unnecessary lights were not left burning where night work was going on or at any time outside of working hours. All electric and gas-heating applications were turned off from 10 to 15 minutes before closing time. Lamps of less candlepower were used for all indicating lamps, and on instruments in the power house.

In order that the peak load, due to lights, should be eliminated, all passenger service on elevators was discontinued when the lighting load came on, and certain heavy machines, such as the coal carrier in the power house, paper calenders, machinery in the carpenter shop, and certain elevators, were shut down at 4 o'clock or thereabouts, and in this manner the peak load due to lighting was largely eliminated.

The total power and lighting load showed practically a flat curve throughout the day.

Many receiving doors and entrance doors were protected by storm porches and by weather-stripping the cracks around the doors to prevent a large amount of cold air from coming into the building. The space between the box frames and the brickwork in all the buildings was closed up to prevent too much air entering in this manner, and weather strips were put on the window sash in many cases where there was bad exposure. In all departments after the lights were turned on the window shades were pulled down to minimize transference of heat through the glass.

A study was made of the use of steam for process work, and exhaust steam was substituted for live steam wherever possible. Instructions were given operators to keep vent pipes closed. More careful inspection was made of all traps, and in many cases automatic return valves were installed to do away with hand control in such cases. The steam was shut off machines some time before closing instead of waiting for the closing gong. In many of the departments the work was laid out so that for certain periods of the day machine work could be done, and at other times the power was shut down.

The use of compressed air was studied, especially with a view to discontinuing its use wherever possible, and the use of the compressed air for cleaning was discontinued.

In obtaining these results it was necessary to interest everyone in the proposition, and means were taken to keep the different groups of employees informed of the savings which had resulted from the changes in operation.

According to the best estimate we could make, taking into consideration our production figures, outside temperatures and quality of coal, we made a comparative saving of 15 per cent. during the year. At our 1916 rate of consumption this would amount to approximately 1350 tons. During the winter months, when we have our greatest coal consumption, we attained by various economies or greatest savings, in some weeks there being as high a reduction as 32 per cent. in our use of fuel.

In reaching these results we reduced the power demand by about 16 per cent., largely through reduction in the lighting load. The reduction in the power load was largely accomplished by rearrangement of working schedules.

Atlas Tack Co., Fairhaven, Mass.

Our first step was to make all windows and doors as nearly airproof as possible and to instruct our watchmen, especially the man who attends to the heating, to look for all steam and air leaks and to report at once in case any of these should exist, that they might receive immediate attention. The factory's temperature was usually from 55 to 67 deg., according to the character of the work done in each department. We installed in our heating steam pipe a steam-recording gage and allowed only a certain pressure, according to weather conditions. In this way the man attending to the heating shifted the heat from one room to another in order to keep the factory comfortable to work in.

We repaired all steam traps thoroughly, so that all condensation was returned to our boilers, and we also covered all exposed steam pipes with 80 per cent. magnesia.

In our pickling and scaling department we installed a steam-reducing valve lowering the steam pressure from 150 to 60 lb., and also placed in the pickling tubs automatic temperature-control valves, making hand regulation unnecessary.

In the eyelet department automatic control valves and thermostats were applied to all japanning ovens to admit only sufficient steam to keep the necessary oven temperature, all condensation being returned to the boilers by gravity, and eliminating all pumping that would otherwise call for considerable power. We covered the tops of boilers with asbestos cement 2½ in. thick, lowering the outside temperature 10 deg. We have installed on all boilers water columns, high- and low-water alarm, preventing wide fluctuation of water level and assuring much better economy. We have also on each of our boilers a boiler-efficiency meter. This shows the firemen at all times the condition of their fires, and has proved a useful and economical instrument.

We installed a V-notch recording and indicating water meter to measure accurately the water pumped to our boilers and show to the boiler-room force the amount of water evaporated per pound of coal.

On account of the limited tube area in our former feed-water heater, we were unable to get the best results from our exhaust steam. These tubes have been replaced by a more efficient set, resulting in 20 deg. increased temperature. At present our feed-water temperature leaving the heater is 130 deg. and leaving our economizer to boilers, 230 deg. Our boiler feed pumps were repaired and put in first-class condition.

In the engine room all valves are set for the highest economy, and we have installed three switchboard recording watt-hour meters. We are about to install a 5-hp. motor to take the place of our steam engines to run the economizer scrapers.

We are installing hand stoker grate bars, which, according to the builders' rating, will give us about 50 per cent. more boiler rating and about 25 per cent. saving in coal.

We have abandoned our old cooling tower and are installing a spray-pond condensing equipment with motor-driven centrifugal circulating pumps.

All boiler settings and brickwork are examined for necessary repairs and tubes in boilers scraped.

I believe that in 1918 our increased efficiency will net us a saving of at least 20 per cent. in fuel.

The George E. Keith Co., Brockton, Mass.

We have a peculiar plant, in that the buildings are widely separated and there is a great deal of heating radiation in all the buildings. The buildings are of wood frame construction and not as tight as they might be. We appointed one man to patrol these buildings three times a day and to record the temperature in each room. This man was made responsible for turning on and shutting off the steam in each department, and in this way we kept the temperatures down to a minimum, so that there was no extra radiation loss.

We have covered every pipe in the entire plant that was carrying high- or low-pressure steam. We have even made it a practice to cover the return pipes. We have experimented to some extent with asbestos covering on the brickwork of the boiler settings. We have covered one boiler to see how the proposition worked out, and undoubtedly will apply this covering to the other boilers. This covering not only cuts down the loss due to heat radiation, but also stops any air leakage, which in the opinion of the combustion engineer is the most serious loss in the entire plant. Air leakage causes a dilution of gases, and we do not get the percentage of CO_2 which gives us maximum efficiency. Consequently, anything which will cut down air leakage around the settings will save coal more than any other method of boiler efficiency.

We were driven to the burning of screenings because we could not obtain soft coal. In fact, we have been burning screenings in some of our boilers for two or three years with good results. We had to install small forced-draft blowers to get results, but have succeeded in burning as high as 70 per cent. maximum of screenings and soft coal.

We have placed traps on every drip or outlet in the entire plant and on the ends of all heating coils. We have arranged our return system of piping so that there is no loss from any of the piping. All the returns come back to our boiler room and are used for boiler feed. This eliminates the expense of makeup water and of course gives us a boiler feed temperature of about 206 degrees.

We have installed a thermometer system whereby the firemen can tell what the temperature is in any building merely by pressing a button. This thermometer is an electric apparatus operated by means of an electrical contact placed in each building.

We have made it a practice to burn all the scraps and waste from the factories.

We have several items for future development, in that plans are being started for a new central heating plant. We now have three isolated heating plants which cause more or less inefficiency, in that the boilers are old and coal cannot be burned to good advantage. We intend to install automatic stokers, weighing devices for recording the amount of coal used, and coal and ash handling apparatus. We intend to lay out our steam mains and steam piping so that all losses will be cut to a minimum.

We have outlined a system of work through our entire plant; are casing up all the windows, making all of the doors tight, and arranging doors so that they will close automatically, thus doing away with any loss from leaving them open. We have placed vestibules inside the factories where we have any shipping doors.

Skilled Enlisted Men To Be Returned to Necessary Industries

In response to appeals from all over the country, the War Department has decided upon a policy that will permit the return to necessary industries of highly skilled men taken from such industries, under a system of furlough which will be automatic and which will not in the future as in the past leave to the discretion of company and other subordinate commanders the question of whether such furloughs shall be granted. Thousands of applications for such furloughs are now being sent out of Washington by various branches of the War Department, in response to the appeals of manufacturers and other producers of war material whose draftsmen, mechanics and other employees, engaged in the past and now upon Government orders for war work, have been taken from them by operation of the draft.

The application blank is as follows:

APPLICATION FOR RETURN OF ENLISTED MAN
IN HIGHLY SKILLED CLASS OF LABOR TO
NECESSARY INDUSTRY

Dated at....................191

Application is hereby made for the return of following enlisted man:

Name.......................... Residence..................
Exact description of trade....................................
Registered local board............Order No......Serial No....
Last reported to camp....................Unit................
Taken into Army..................191, because...............
....
....
We ask that he be directed to report to......................
....
We have the following direct Government contracts:

Date	Gov. Order No.	Quantity	Description	Dept. of Gov.
......	....	......	....	....
......	....	......	....	....
......	....	......	....	....

We are under contract with the following, who have direct Government contracts from............................Dept.......
....
....
We have established our status as "necessary" industry with District Board No....... of State........located at............
....

By......................(Title)

Sworn to before me at.............
this........day of...............191

....
....
Title of official administering oath.

I have checked the foregoing statements and have found them to be correct.

....
....
Local representative of..................................Dept.

The adoption of the new policy means that enlisted men are to be returned to industry only in cases where the drafted man's employer is willing to swear that the man is badly needed and that no one can take his place. The Government department for which the manufacturer or other employer is working will, upon application, send one of the blank forms to the employer, which he must fill out, swear to before a notary, and have a Government inspector who is conversant with the facts also sign. The signed application then goes to the Adjutant General's office, with request from the interested Government department that the man wanted be granted an indefinite furlough, without pay, with the promise that after the need for the man's service has passed he will be returned to the Army.

While such men are on furlough they are not to be allowed to wear the uniform. The company employing them must furnish the Government each month a report that they are still in employment and the class of work engaged in. In case such men leave their employment, the employers must immediately notify the Government.

Thousands of applications for furloughs for enlisted men in necessary industries have recently reached Washington, and Washington has been unable to grant permission for the necessary furloughs because company commanders and other subordinate officers could not be convinced that certain of their men might be more necessary in civil life than in the ranks. The Adjutant General's office has sent a circular to heads of War Department divisions permitting the new system. The Government is protected, from the army-in-the-ranks point of view, by the fact that wherever a fraud is perpetrated or attempted a sufficient number of persons will be familiar with the circumstances to result in the War Department being notified.

Skagit River Development

The Seattle City Council has definitely decided to proceed with the development of the Skagit River power site, which has been offered to the city free of cost, and all bids for the sale of other sites and the construction of plants for the city have been rejected. As soon as the necessary plans can be completed, bids for the work will be called for by the Board of Public Works, C. B. Bagley, secretary.

Covering in every detail the construction of the proposed hydro-electric power project on Skagit River, Superintendent of Lighting J. D. Ross has submitted to the Board of Public Works a report which shows the initial cost of the first development to be $4,712,080. These figures include the 103-mile transmission line necessary, with an estimated cost of $1,214,000. The summary of the report follows:

The total available power on this river, without storage at the lower or Gorge Creek plant, is 900 cu.sec.ft., capable of developing 25,000 hp. continuous 350-ft. head. The total available on the stream for three plants without storage is 900 cu.sec.ft., capable of developing 65,000 hp. continuously.

After impounding the water by Ruby dam, the equalized flow of the river is estimated to be 4000 cu.sec.ft., capable of developing 289,000 hp. About 350 square miles out of the drainage area of 1100 or 1250 square miles is on the Canadian side.

As far as known none of this can be economically diverted, but no data have as yet been obtained on the Canadian side. For this reason and to be sure of possible low-water years we base our estimates on 200,000 continuous horsepower instead of 289,000. The drainage area is the largest of any Washington power site, being estimated at the lowest to be 1090 square miles and the highest estimate gives 1250 square miles.

The total available fall of the river is 950 ft. and the site lends itself admirably to a successive development in three steps.

The transmission line is 103 miles to the north city limits. The voltage would be 110,000, and the loss in transmission with both lines operating will be 5 per cent. at full load of 50,000 hp. Our estimate includes two lines on steel towers the entire distance. The entire works of the three plants, including foundations, tunnels, the three concrete dams and all reservoir capacity, is set in rock. The tunnels are flow-line tunnels only, being under less than 100 per cent. pressure at any place.

The lowest tentative bid received on this project is $2,381,000 for 50,000 hp. installed, being a price of $47.62 per horsepower. The Cedar original plant, one of the most economical in America, cost $57.74 per horsepower. Estimating $1,240,000 for two transmission lines on steel towers and $275,000 for substations, the cost per horsepower on this bid would be $81.52 per horsepower in Seattle. The Cedar River plant, including substation, cost $95.55 per horsepower.

This estimate includes a diverting dam 25 ft. high and a flume and tunnel 12,000 ft. long.

The dam can be raised to elevation 850 ft., making it about 100 feet high. The rock is exposed on both sides at the best location. The plant then becomes entirely permanent. This permanent plant will cost about $3,499,000 for 50,000 hp. This is $69.98 a hp., installed. With transmission lines and substation all permanent steel and concrete construction, the cost will be $4,998,080, or $105.01 per horsepower ready for distribution at Seattle.

The report of City Engineer A. H. Dimock on the same project states:

The average cost a delivered horsepower of the various projects considered by the city, as follows: Stillaguamish River, $124; Wallace River, $132; Packard Lake, $224, and Skagit River, $105.

Considering the merits of the Skagit River power proposition, however, due allowance must be made for the value of the undeveloped power. On the most conservative basis there is available in this river a total of 289,000 hp., or 230,000 hp., in addition to the 50,000 hp. to be considered in this statement. It is entirely probable that further study of the capacities of this river may show a still larger amount.

The above is based on the lowest flow record obtainable. The value of a horsepower installed of undeveloped power is, of course, difficult to determine. In a discussion on the development and operation of hydroelectric plants in the proceedings of the American Institute of Electrical Engineers for the year 1909, it is stated that the value of land and water rights would average about 10 per cent. of the cost of a horsepower installed, or in this case $10 per horsepower. If this assumption be correct, the value to the City of Seattle of the power possibilities on the Skagit River, which may be obtained without any cost whatever, will be nearly $3,000,000.

All the items entering into these plants will be of the most permanent and durable character. The dams would be of concrete on rock foundations and with rock sidewalls. The water would be conveyed from reservoirs to power house by tunnels through the mountains, also constructed in solid rock. The power houses and equipment would be of the safest possible construction.

It has been shown by the foregoing figures that the present cost of the development of the Skagit River is lower than that of any other, and that it has possibilities for future development and for supplying the power needs of the city for many years to come.

The acquisition of this project and its development as needed will enable the City of Seattle to supply power to its customers at the lowest possible rates. There can be no question that the Skagit River affords the finest opportunity to the City of Seattle, both for present and future needs.

N.E.L.A. Convention at Atlantic City

The National Electric Light Association, as announced in a previous issue, will hold its annual convention at Atlantic City, June 13 and 14, the tentative program of which is as follows:

Thursday Morning, June 13—Presidential address; reports of secretary, treasurer, membership committee; reports Commercial, Technical, Accounting and Electric Vehicle Sections; new business. Thursday afternoon—Report of National Commitee on Gas and Electric Service; report of committee on public utility conditions—war financing of utilities, rate increase activities, etc.; report of public policy committee; discussion of central-station aspects of the labor problem; female employment; meter reading and testing; economized accounting. Thursday evening—Patriotic addresses on the broader national topics of immediate importance to the industry, by distinguished speakers (details in the hands of the president). Friday morning, June 14—Address and general discussion on the coal situation; important war-time topics introduced by the Technical and Hydroelectric Section. Friday afternoon—Important war-time topics introduced by the Commercial, Accounting and Electric Vehicle Sections. Friday evening—Round-table discussions and films of war activities of special interest to member companies, with other appropriate features.

Convention headquarters will be at the Hotel Traymore. Hotel reservations are in the hands of Frank W. Smith of the convention committee, 130 E. 15th St., New York.

Pleasure Yachts May Be Deprived of Fuel

It is probable that the United States Fuel Administration will issue soon an order prohibiting the use of coal and fuel oil by private yachts—meaning any vessel operated not for profit.

Incomplete figures now in hand show an average in commission for the last three years of 282 private yachts driven by steam and more than 1000 driven by gasoline. The total fuel used in these vessels has been deemed worthy of consideration at a time when a shortage of fuel is inevitable. The elimination of these craft would also release a considerable number of men for work in the war industries.

It has been shown that hundreds of vessels formerly operated as private yachts have been turned over to the Government for use in the war.

Navy Needs at Once One Thousand Gas-Engine Men

The Naval Reserve Force must enroll at once 1000 men experienced in the operation and maintenance of gasoline engines. This is an urgent call. The men are required for immediate duty. They will be rated as machinist's mates.

Age limits are 18 to 35 inclusive. Applicants must be American citizens. Draft registrants with letters from their local boards will be accepted.

Apply at Naval Reserve Enrolling Office, 51 Chambers St., New York City, or any navy recruiting station.

Cent-a-Gallon Gasoline Dream Ended

Robert H. Rohde, in the New York *Tribune*, May 5, 1918, gives a very illuminating and lengthy history of Louis Enricht, of Farmingdale, L. I., and his "One-Cent-a-Gallon Gasoline," under the title, "The Amazing Tale of a Cent-a-Gallon Sorcerer." No doubt many of the readers of *Power* will remember how this Louis Enricht sprung into public attention overnight, back in 1916, when he announced to the world that he had discovered how, by mixing a small amount of a green liquid, compounded by himself, into a quantity of water, the latter was immediately converted into a motor fuel equal to gasoline. According to Mr. Rohde's narrative, the early demonstrations of Mr. Enricht's invention were made on a so-called cycle car, and were of a nature as follows:

A bucket of water would be supplied from an old pump, then the witness would be invited to drink of the contents of the bucket, which invariably proved to be plain water. This same water was used to fill the tank of the cycle car. A small bottle containing a green fluid would be shaken over the mouth of the tank. The mixture in the tank would be stirred and the cap affixed. A twist of the crank would start the engine with a curl of vapor that smelt vaguely sweet shooting from the exhaust. Your attention was invited to the odor of the vapor. Then off you went to experience just the same sort of ride you would have had if you had been covering the same road in a cycle car by gasoline.

Perhaps there would be a little of the fuel left in the tank when you returned. Enricht would drain it at once through a pet cock and watch it disappear into the earth. "I must be careful," he would say, "if a few drops of the fluid gets into other hands, my secret is gone. It is easy to analyze, and I do not know how I shall protect it." When you talked it out with him and considered the problem from the inventor's view, this was one of the great arguments for secrecy, a valid reason why there might be delay to giving the boon of "Cent-a-Gallon Gasoline" to the public.

How could the secret be protected? That was the question. The ingredients, Enricht explained, were simple. They could be bought at any drugstore. A child could mix them in the proper proportions. There was nothing to prevent automobile owners from doing that very thing.

Then along came Henry Ford, who "joyrided" many a mile under the impulse of the Enricht fluid. He hunted and hunted for the joker but couldn't find it. He put Enricht in possession of a brand new flivver, straight from the shops; and Enricht poured water into its in'ards and added a little of the green stuff, stirred the mixture, turned the crank and off he and Henry went. But one day found this a closed incident. Henry had seen "Cent-a-Gallon Gasoline" in operation. He had been for a time convinced of its revolutionary merits. He had openly referred to Louis Enricht as a great man. It was said he had made a magnificent offer for the secret, planning perhaps to publish the full history as a benefaction to motor drivers. Maybe the offer wasn't magnificent enough; maybe Ford suffered a change of heart and mind and withdrew it.

He and Enricht parted. They were not friends. Ford sued Enricht for the return of the flivver which had figured in the demonstrations. Officers of the law under due process removed the flivver from Enricht. The old inventor immediately began action against his erstwhile crony. It seems he had substituted for the Ford engine one of his own, so the replevined flivver wasn't really Ford's property at all. And in that litigation Enricht dropped out of sight once more. Some weeks, or some months, passed, then entered B. F. Yoakum.

Enricht and Yoakum had been neighbors. Yoakum was the rich man of Farmingdale. The National Motor Power Co. was organized with Enricht and Yoakum in control. To the company Enricht assigned his secrets in exchange for stock. Now he says that stock was all he got—and all the company had. He insists that the whole capital of the enterprise lies in the value of the secret he had to sell.

As he had fallen out with Ford, so Enricht fell out with Yoakum. In this case a formal offer appears to have been made by the British Government after a protracted period of tests. It was because of a secret sympathy with Germany, the plaintiff alleges, that Enricht would not deal with Great Britain.

The affidavits filed at Mineola were most interesting. They recited how in months of demonstration in the laboratories of the Automobile Club of America Enricht had run engines he had never seen before, engines that could not possibly have been tampered with, on this fuel. Experts had watched every move he made. Moreover, it was asserted that the fluid was no longer the complete mystery of the early days. Yoakum had kept pressing Enricht, demanding as a business associate, his closest confidence. He insisted that the secret should become the property of the National Motor Power Co. And in a measure Enricht had given way. He had made public, at least within the circle in which sat Yoakum and the British experts, a list of ingredients entering into the compound, withholding only one element.

The ingredients were, as he said, common. The experts had bought them and compounded them, leaving it for the inventor to complete the fuel by shaking into each tankful a few drops of liquid from a little vial that never left his possession. Without this liquid the compound gave only slight evidence of motive power.

That little private bottle never left Enricht's possession, but one day it almost did. According to his own story, he had been lured into a deserted road near Farmingdale one day and had found himself confronted with armed men who demanded the bottle, which Enricht at length produced. However, it seems that Enricht had been prepared for some such contingency as he met on that lonely road, for according to his story he had provided himself with a duplicate bottle and it was the dummy he surrendered to the holdup men.

The foregoing is just another one of the questions that keep cropping up at every turn with Enricht and his fuel. However, at every turn he has kept himself covered.

Within the near future the case of Yoakum vs. Enricht must be coming up. Then it will rest with the courts whether Enricht shall be ordered to give to the National Motor Power Co. his full secret.

In the pendency of the suit, Enricht, by his own statement, has been in conference with Secretary Baker and Attorney General Gregory. He asserts the United States Government has made him an offer in excess of that made by the British Government, contingent, of course, on his fluid being all he claims it to be.

"The Government wants my secret only for war use. What I want the Government to do is to protect me after the war. I propose that I should be especially licensed to manufacture the compound, and that it be illegal for anyone else to make it. On that plan I was ready to sell my fuel to the Government for 10c. a gallon and to sell to the general public at 12c. a gallon, of those sales pay a tax of 2c. a gallon and enriching the Treasury at the rate of something like $70,000,000 a year."

So the "Cent-a-Gallon Gasoline" idea has been abandoned. Enricht explained that the cost of chemicals he needs has greatly advanced within the last two years.

"They have had the wrong idea from the first," he says. "Their theory is that I change the chemical composition of water, and they say truly that I must spend more energy in the process than would be produced. As a matter of fact, water is just a carrier. It takes minute quantities of my high explosive through the carbureter into the cylinder. Simple? Eh?"

Thus ends the dream of "One-Cent-a-Gallon Gasoline."

John Coats Takes a Bath

According to the *Electrical Experimenter*, all institutions depending upon the Marion (Ind.) Electric Light and Power Service were without current for a minute recently, and all because John Coats, who takes his regular Saturday evening bath at his home, got hold of a live wire in attempting to shake into life a defunct electric-light globe, and could not let go. Standing in the water with a 110-volt current coursing through his body, all Coats could do was to yell for help. A neighbor quickly discovered his plight, and telephoned the light company, who turned off all current. Coats was injured only in feelings.

Tar Oils for Use in Internal-Combustion Engines*

By A. Vincent Clark

The different classes of both solid and liquid fuels vary greatly in their calorific value. Some crude oils have a calorific value of about 20,000 B.t.u., whereas the heat value of tar oil is only approximately 16,000 B.t.u.

The various groups of liquid fuels show great differences during the process of combustion, and those rich in hydrogen are much more readily combustible than those deficient in this constituent, which is the case with tar oil, with the result that it cannot have a perfect gasification and combustion. Crude tar and the thick tar of gas-works are really intermediate between liquid fuels and coal, and usually the liquid requires some refining before being suitable for use as fuel for internal-combustion engines.

The accompanying table gives a comparison of the composition of various fuels as regards their percentage of carbon and hydrogen.

COMPARISON OF COMPOSITION OF VARIOUS FUELS

	C Per Cent.	O Per Cent.	H Per Cent.	Free H Per Cent.	Molecular Ratio H/C
Benzine	84.5	0.5	15.0	15.0	2.13
Petroleum-oil gas	85.0	2.0	13.0	13.0	1.84
Benzol (C_6H_6)	92.3	—	7.7	7.7	1.00
Tar oil	87.0	5.5	7.5	6.8	0.94
Heavy tar	86.0	9.0	5.0	3.9	0.54
Coal (flaming)	85.0	9.5	5.5	4.3	0.60
Coal (caking)	88.0	7.0	5.0	4.1	0.56
Lignite	64.0	30.0	6.0	2.2	0.41
Anthracite	94.0	3.0	3.0	2.6	0.33
Wood	50.0	44.0	6.0	0.5	0.12
Cellulose	44.4	49.4	6.2	0.0	0.00

Tar oil suitable for use in Diesel engines should have a specific gravity at 60 deg. F. not to exceed 1.1, calorific value not less than 15,700 B.t.u., fluid at 60 deg. F., and a maximum content of water, coke and ash not exceeding 2, 5 and 0.1 per cent., respectively.

Tar oils have been successfully used on some makes of Diesel engines without alteration being necessary to the engine, but more frequently cleaning is usually required when this oil is used and the pulverizers should be cleaned about every 100 hours. The carbon deposit is generally not very difficult to remove and can easily be cleaned off with a blast of air.

It has been found that engines work better on the tar oil when the load is fairly uniform, and less cleaning is required if they are able to keep running continuously at about full load. It is always necessary to start the engines on refined or light crude oil, and if they have to run with a light load, this oil must be continued until the load is increased. No alterations are needed to the setting of the valves whether the engines run on petroleum or tar oil, but in some cases it has been necessary to alter the flame plate of the injection valve to give a sharp edge around the orifice. It is advisable not to turn on tar oil until the jacket-water temperature has reached at least 120 deg. F., and in cold weather it is advisable to pre-heat the tar oil before it enters the fuel pump.

Attempts have been made to run engines with mixtures of refined or crude petroleum and tar oil, but such mixtures have been found liable to produce trouble, probably because of the oils separating out in the tank or distributing pipes, owing to the difference in their specific gravity, so that the actual fuel passing into the cylinders is not of uniform quality. This has been found to be especially the case in cold weather, but the difficulty is quite overcome by using separate pumps and pipes for delivering the two oils separately right up to the injection valve, and this system has been successfully employed on the Mirrlees Diesel engines.

The Mirrlees engine has been adapted to run on tar oil by the employment of what may be termed an ignition oil, which may be refined or light crude, and a small quantity of this latter oil is admitted before the tar oil in order to start combustion. This ignition oil is only about 5 per cent. of the amount supplied. Combustion begins, and the temperature of the gas inside the cylinder is raised by the burning of the ignition oil, so that as the heavier tar oil is immediately afterward injected into the combustion space it is at once ignited, the temperature being high enough to allow proper combustion. The method which is adopted involves the using of two separate pumps, one supplying ignition oil and the other tar oil, the latter being under the control of the other. The two oils enter the fuel valve by different passages, and the ignition oil is admitted as nearly as possible at the bottom of the needle. By this means the lighter fuel is first injected into the cylinder and the arrangement gives quite satisfactory combustion of the tar oil, so that practically an invisible exhaust is obtained. This method of injecting the fuels also reduces the amount of carbon deposit in the combustion space, and the valves and pistons show remarkable freedom from deposits, so that they do not require much more attention than is ordinarily given to these parts.

The engines of the semi-Diesel type may also be run successfully with tar oil as fuel by using an ignition oil, but these engines need an increased amount of the latter, varying according to the design, up to approximately 30 per cent. Upon running them on tar oil it is found that after they have been working for some time at about full load, the amount of ignition oil can be reduced, provided the load remains constant, and in some cases entirely cut out. Probably this feature can be explained by the formation of carbon in the combustion chamber remaining incandescent, and thus serving to ignite the incoming charges of tar oil.

Generally speaking, the hot bulbs need cleaning every day, as a large amount of deposit accumulates in them, which if not removed will make the engine difficult to start and there is a possibility that the bulbs will eventually become completely choked. In addition these engines are much more susceptible to changes in the quality of tar oil than engines employing high compression.

---

*Abstract from an article in the April issue of "Gas and Oil Power," London, England

Applications for Water Appropriations

Applications have been filed with the California State Water Commission for the appropriation of water for the generation of power by the following:

The Nevada-California Power Co., of Riverside, Calif., has applied for 12 sec.ft. of Birch Creek in Inyo County for the generation of electric energy to be developed at existing power plants Nos. 2, 3 and 4, by falls 913, 791 and 995 ft., respectively, the horsepower to be developed being 1244, 1079 and 1356, respectively. After use it is proposed to return the water to the Hillside Water Co. The estimated cost of the works is $42,500.

The Southern Sierras Power Co., of Riverside, Calif., has applied for 12 sec.ft. of Birch Creek when said water may be available, for the generation of electric power at existing plants Nos. 5 and 6 of this company. It is proposed to develop 500 and 513 hp. by falls of 366 and 230 ft., respectively, the water to be returned after use to the Hillside Water Co. The estimated cost of the works is $42,500.

Chicago Edison Company's Off-Peak Rates

Some of the figures given on page 747 of *Power* for May 21 do not correctly represent the off-peak rates of the Commonwealth Edison Company of Chicago. George H. Jones, power engineer of that company, states that for off-peak business a limited-hour contract is offered, modified by a rider which provides for an annual guaranty of $24 per kilowatt of demand required. The contract is on the demand basis, the off-peak demand charge being $1.40 per month per kilowatt for the first 25 kilowatts and 90c. per month per kilowatt for excess. The energy charge is 3c. per kilowatt-hour for the first 5000 kw.-hr. of consumption per month; 1.3c. for the next 25,000 kw.-hr.; 1.1c. for the next 70,000 kw.-hr.; and 0.9c. for over 100,000 kw.-hr. A cash discount of 10 per cent. is allowed on the energy charge.

Men Wanted for Submarine Duty

It is desired to call the attention of young men who have had technical training and experience to the fact that their abilities can best be put at the service of the country by selecting a branch of service in which their special qualifications will be of the greatest use.

The Submarine Force of the United States Navy requires the services, as officers on board submarines, of young men who have had technical training in mechanical and electrical engineering and who have had experience in these professions. It is intended to enroll a number of such men as provisional ensigns in the Naval Reserve Force, give them a course of instruction in deck duties at Annapolis and a course in submarine work at New London. Those who successfully pass these courses will then be sent on board submarines for regular duty.

It is requested that any men who desire this duty and who are qualified as below outlined, send their names and addresses to the Commander Submarine Force, U. S. S. "Chicago," care of Postmaster, New York. Qualifications required: Desire to serve in submarines; degree of M. E., E. E. or E. M.; 2½ years' practical experience in profession; not over 35 years old; physically strong and sound. Candidates should, if practicable, receive the indorsement of one of the following organizations: Naval Consulting Board, National Research Council, American Society of Mechanical Engineers, American Institute of Electrical Engineers, American Institute of Mining Engineers.

Government Calls for Thousands of Technical Men

You may hit the Hun without going to France. In other words, the great army of specialists behind the men behind the guns, working in connection with the production of the material of war, are quite as necessary as the actual fighting forces in the prosecution of the nation's greatest undertaking. The United States Civil Service Commission, whose duty it is to recruit the civilian forces, announces that the War and Navy Departments are badly in need of large numbers of technically trained men. The commission urges, as a patriotic duty, that qualified persons offer their services to the Government at this time of great need. Among the positions now open are the following:

	Usual Entrance Salary
Automotive engineer	$2,400 to $7,200 a year
Automotive designer	1,800 to 3,000 a year
Automotive draftsman	1,400 to 2,000 a year
Automotive tracer	1,000 to 1,400 a year
Expert in motor-vehicle standardization	1,600 to 3,000 a year
Mechanical engineer	3,500 a year
Junior mechanical engineer on high-pressure apparatus	1,600 to 2,400 a year
Mechanic experienced on high-pressure apparatus	3.00 to 5 00 a day
Inspector of mechanical equipment	2,700 a year
Inspector of structural steel	2,400 a year
Inspector of laundry machinery	1,800 a year
Operative in gas manufacture	1,600 to 2,400 a year
Assistant operative in gas manufacture	3 00 to 5.00 a day
Superintendent of high-explosive and acid plant	1,500 to 1,800 a year
Marine-engine and boiler draftsman	3.28 to 7 04 a day
Metal-furniture draftsman	4 00 to 6.00 a day
Engineering draftsman	3 04 to 7 04 a day
Mechanical draftsman	4 00 to 8 00 a day
Apprentice draftsman	480 a year
Refrigerating engineer	3,000 a year

A further long list of technical positions in the War, Navy and other departments are to be filled. For the positions named applicants are not required to report at any place for examination, but are rated upon their education, training and experience, and in some cases on work submitted with the application. Physical ability is also considered in some instances. Ratings are arrived at from information set out in the application blank and from corroborative evidence.

The Civil Service Commission calls particular attention to the fact that all necessary information concerning civil-service positions, and application blanks therefor, may be obtained free of any cost by applying to the commission's representative at the post office in any important city, or by addressing the United States Civil Service Commission, Washington, D. C. Many of the drafting positions are open to women.

Will Tie-In Three Electric Companies

At a recent meeting of the representatives of the Pacific Gas and Electric Co., the Northern California Power Co. and the California-Oregon Power Co. and the members of the California Railroad Commission, at Sacramento, Calif., the details were completed for the "tie-in" of the three companies to effect a full utilization of the hydro-electric facilities of Northern California. As a result, the three companies will immediately start construction on transmission lines to connect up the systems of their respective companies at a total cost of $640,000.

The California-Oregon Power Co. will connect its system up with that of the Northern California Power Co. by reconstructing its transmission line from the plant at Copeo to Castella and by building a 70,000-volt transmission line from Castello to Kennet, a distance of 90 miles. The estimated cost of this work is placed at $330,000. The Northern California Power Co. is to reinforce its lines from Colman to Hamilton, a distance of 80 miles, by the addition of copper conductor of sufficient capacity to handle a load of 8000 kw. throughout the year. The work to be done by the Pacific Gas and Electric Co. includes the construction of a 60,000-volt transmission line from Colusa Corners, near Colusa, to Drum-Cordella, a distance of 40 miles, and the installation at their substation of from 60,000 to 100,000 volts capacity to deliver power into that line.

The entire project is to be completed by Sept. 1, according to the present plans, and it is estimated that as soon as the surplus power from the northern part of the state becomes available the load taken from the steam-generating plants will be such as to effect an economy in the use of fuel oil to the extent of 240,000 bbl. per year.

As soon as the "tie-in" is effected, the Pacific Gas and Electric Co. will be required to reroute power from certain of its existing plants over Wise-Stockton-Mission-San José line to the southern district now served by the company.

Steam and Water Packing and Rubber for Chile

Consul John R. Bradley states in *Commerce Reports* that the American consulate at Punta Arenas, Chile, is desirous of being supplied with catalogs of steam and water packing, sheet rubber and sheet asbestos. There is quite a large demand there for all kinds of packing. This is the home port for some 20 small steamers plying in the coasting trade, besides which there are five meat freezing and packing plants, several sawmills, an electric-light plant, and a canning works; also a coal mine. The purchasing agents in most cases understand English, and catalogs may be furnished in that language. To prevent delay in making these firms acquainted with American products a list of users of steam and water packing and sheet rubber in Punta Arenas, to whom catalogs should be sent direct, may be procured from the Bureau of Foreign and Domestic Commerce or its district and coöperative offices upon referring to file No. 99693.

Use of Bran for Fuel in Argentina

According to the *Commerce Reports* one milling company in Argentina at present has a daily production of about 280 tons of bran, but there is practically no local market for it as stock food, and it cannot be exported because of the lack of shipping. Nearly all of it is used for fuel. The company itself burns about 100 tons per day, and this replaces some 60 tons of coal, which was formerly used. According to Mr. J. Buelinckx, general manager of the company, bran gives about the same result as wood. The remainder of the output of this establishment—about 180 tons a day—is sold to various concerns for fuel. The present price is 28 pesos per metric ton, and this is somewhat cheaper than wood. The company is experimenting in making briquets of bran, but as yet has not commenced their manufacture upon a large scale.

The Future of Water and Steam Power

The following is from lectures prepared by Prof. L. P. Breckenridge as part of his fuel-conservation work for the Fuel Administration.

The development of water power in this country will be gradual. Our coal supplies are vast, and we shall use coal for power production. We shall need 50,000,000 hp. by the year 1930, and of this amount, one-fifth should be water power, or 10,000,000 hp., leaving 40,000,000 hp. to be made by burning coal. This power is probably in excess of our total available potential water power. The writer believes that we might increase our production of power by 12,000,000 hp. without the consumption of any additional coal. To accomplish this, we should expect to assign to water power a development of 4,000,000 hp. This would leave 8,000,000 hp. to be developed by burning coal. It would mean the adoption of more economical equipment on the one hand and more economical methods of procedure and operation on the other.

From a chart, "Power Development in the United States," the following figures were taken:

POWER DEVELOPMENT IN THE UNITED STATES

Year	Millions of Horsepower		
	Water	Steam	Gas
1870	1 10	1 35	...
1880	1 12	2.40	...
1890	1 25	5.00	...
1900	2 20	14.00	0.4
1910	5 25	23 50	
1920*	(9 00)	(33 00)	

* Extended.

While it is not possible to determine with great accuracy figures such as given, it is sufficient to indicate the fact that the total power development in the United States is very great, and that the percentage of the total power now being developed from water fortunately is increasing.

As an indication of present tendencies, it may be well to mention a few of the more important water-power developments that have been completed within recent years, including also the installations at Niagara Falls:

Power Companies at Niagara Falls	Installation, Horsepower
On American side:	
Hydraulic Power Co., of Niagara Falls	144,000
Niagara Falls Power Co	118,300
On Canadian side:	
Ontario Power Co., of Niagara Falls, Ontario	120,000
Canadian Niagara Power Co	62,500
Electrical Development Co., of Ontario (limited)	52,000
International Railway Co	3,000
Total	499,800

The "Salmon River," N. Y., 30,000 hp., under 235-ft. head.

The "Tallulah Falls," Ga., 70,000 hp., under 580-ft. head.

The "Ocoee River," Tenn., one of 27,000 hp., under 110-ft. head, and another 30,000 hp., under 272-ft. head.

The "McCall Ferry," Susquehanna River, ultimate capacity 135,000 hp.

The "Coons River," 13 miles above Minneapolis, 3500 hp. under 17½-ft. head. "Keokuk," Iowa, Mississippi River, present 120,000 hp., ultimate capacity 300,000 hp. under 20-39-ft. head.

The "Pitt River," Mt. Shasta, Redding, Calif., ultimate capacity 200,000 hp., under 939-ft. head.

The "Klamath River," Thrall, Calif., present 10,000 hp., ultimate 53,000 hp. Head not given.

"Big Creek," P. L. and P. Co. to Los Angeles, present 60,000 hp., ultimate 400,000 hp., 1900-ft. head, 15,000 volts, 241 miles transmission.

The price at which power is sold to the consumer depends upon several important factors: (a) The cost of producing the power, (b) the cost of distributing, (c) the amount purchased by the consumer, (d) the amount available at any one time for the consumer, (e) the time at which the power must be used, (f) the extent of coöperation between the producers and users of power, (g) the cost of administration.

At Niagara Falls large quantities of power are sold at \$20 per hp. per year, which is about 0.3c. per kw.-hr. This power is sold near the falls, and the distributing cost is therefore small.

In Toronto, 90 miles from Niagara Falls, the city buys large blocks of power at \$18.50 per hp. and sells 10-hour power at \$28.

In Norway, where the great air-nitrate industries consume large amounts of power, the price is said to range from \$1.90 to \$12 per hp. per year.

In this country steam-generated power is made and sold at prices ranging from \$30 to \$150 hp. per year for 10-hour power. If the plant capacity is 1000 hp. or over, the cost of power need not be more than \$25, with the price of coal at \$4. The cost will, of course, increase for the smaller plants, but may be as low as \$15 for larger plants (3000 hp.) and coal at \$2 a ton.

Test Electric Welding for Ships

A report of the purposes and possible benefits of the ship-welding test now being conducted by the Emergency Fleet Corporation at the Federal Shipbuilding Co. plant at Newark, N. J., under the direction of Arthur J. Mason, has been made to Charles Piez, vice president of the corporation.

The text of Mr. Mason's report follows in part:

Electric welding in its various phases has for years been employed in shipyards and in the arts generally, but for a number of reasons the work has been confined to odd jobs and repairs and the test itself will take the form of building part of a hull at the Federal Shipbuilding Co.'s plant, Newark.

It has been necessary to design a ship to suit the material available, without encroaching on that needed for the regular ship construction at the plant. This has been done. The hull will have the outline, dimensions and strength conforming to the ships the Federal company is building.

Briefly, the program is to assemble a hull rapidly by spot welding, tacking the ship together. After the material is thus assembled and fastened with spot welds, so that it is sufficiently strong to hold its shape, the work is completed by arc welding all seams to insure strength and render the work water-tight. Roughly, the spot welds are expected to be about 10 in. apart.

Electric welding offers a great field for lightening a ship. In this design various views of this opportunity will be tried out. The field here is very great—ultimately 10 per cent. of the steel may be eliminated.

The manufacture of the spot-welding yoke and appliances is placed in the hands of the Universal Electric Welding Co. of Long Island City. The design of the yoke is completed, the patterns are made and steel castings will be forthcoming in a few days. The early stages of the arc welding are to be accomplished by the Wilson Electric Co., which was so successful in the work on the German ships' repairs, but it is the intention to call in all men with ideas and apparatus and to give them a field to test out in actual work. To this end Professor Adams' committee is searching out all available talent.

An adequate system of testing the work when done is under consideration. The primary test will consist of filling the hull with water and shifting the points of support under continual and close scrutiny, as one-quarter of the whole will be riveted in the normal manner. There will be always a gage of comparison with that portion which is welded.

Likewise there will be a chance for comparison of the two forms when subjected to abuse by bumping with rams and in various other ways.

Queer Notion of Factor of Safety

On a recent trip to a remote part of the state, one of the boiler inspectors of the Industrial Accident Commission found an installation which was, to say the least, unique. The boiler was of the vertical tubular type, 30 in. in diameter, and was fitted with a ball-and-lever safety valve. In addition to the ball weight, the lever carried four large-sized horseshoes. Upon inquiry it developed that the operator of the boiler thought he had a factor of safety of 5, since he carried only 40 lb. pressure, and the steam gage was graduated to 200 lb. Any idea that the horseshoes were a symbol of good luck, was soon dispelled by the inspector, who pointed out the grave danger of "loading" the safety valve.—*California Safety News.*

According to Mr. Knudsen, manager of Burmeister & Wain, builders of Diesel motors in Copenhagen, fish oil will make an excellent fuel for Diesel engines used as prime movers. Further, this oil will be practicable for small fishing boats where explosion-type motors are used for motive power. It is interesting to note that experiments have already been made, using fish oil as fuel in fishing-boat engines, and that these experiments have proved successful. —*Commerce Reports.*

Heating Values of Fuels

The following tables are from lectures prepared by Prof. L. P. Breckenridge as part of his fuel conservation work for the Fuel Administration.

TABLE I. RELATIVE HEATING VALUE OF WOOD AND COAL

Kind of Wood	Weight per Cord in lb.	Heating Value B.t.u. per lb.	Equivalent Weight of Coal of 13,500 B.t.u
Ash	3520	5450	1420
Beech	3250	5400	1300
Birch	2880	5580	1190
Cherry	3140	5420	1260
Chestnut	2350	5400	940
Elm	2350	5400	940
Hemlock	1220	6410	580
Hickory	4500	5400	1800
Maple, hard	3310	5460	1340
Oak, live	3850	5460	1560
Oak, white	3850	5400	1540
Oak, red	3310	5460	1340
Pine, white	1920	6830	970
Pine, yellow	2130	6660	1050
Poplar	2130	6660	1050
Spruce	1920	6830	970
Walnut	3310	5460	1340
Willow	1920	6830	970

TABLE II. APPROXIMATE HEATING VALUES OF DIFFERENT COALS

Fuel	Heating Values B.t.u. per Pound
	(varies)
Wood (dry)	5.500–7,500
Peat (air-dried)	about 7.500
Lignite	5,200–7,500
Bituminous coal	9,500–14,500
Anthracite	11,500–14.000
Straw	about 5,100
Corn	7,200–8,200
Tanbark (dry)	about 6,100
Hydrogen	62,000
Crude oil	17,500–21,000
Kerosene	0.863 sp.g.–18,700
Gasoline	0.710 sp.g.–18,500
Natural gas	About 850 per cu.ft.
Producer gas	About 125 per cu ft.
Blast-furnace gas	About 95 per cu.ft.

Constants for Heat Transmission

B.t.u. transmitted per square foot per hour per degree difference in temperature between inside and outside air are as follows:

CONSTANTS FOR BRICK WORK

4 in. thick = 0.68
8 in. thick = 0.46
12 in. thick = 0.33
16 in. thick = 0.27
20 in. thick = 0.23
24 in. thick = 0.20
28 in. thick = 0.18
32 in. thick = 0.16
36 in. thick = 0.15

MISCELLANEOUS CONSTANTS

Reinforced concrete, 20 per cent. more than brick. Add one-third more for stone. Add one-half more for cement or concrete walls.

1 sq.ft. of wood as flooring	0.083	1 single skylight	1.118
1 sq.ft. of wood as ceiling	0.104	1 double window	0.560
1 sq.ft. of wood as wall	0.220	1 double skylight	0.621
1 sq.ft. fireproof flooring	0.124	1 door	0.420
1 sq.ft. fireproof ceiling	0.145	Cor. iron wall	0.840
1 sq.ft. cement as flooring	0.310	Wood wall	0.280
1 sq.ft. dirt as flooring	0.230	Copper, silver-plated and polished	0.02657
1 sq.ft. wood, under slate, or composition roof	0.300	Copper, polished	0.03270
1 sq.ft. wood, under iron	0.170	Zinc and brass, polished	0.04906
1 sq.ft. tile (no bds.underneath)	1.250	Sheet iron	0.08585
1 sq.ft. cement roof	0.600	Cast iron, new	0.6480
1 single window	1.090	Cast iron, rusted	0.6868
1 single monitor	0.950	Oil or varnish	1.4800

The amount in square feet of each kind of surface is to be multiplied by its respective constant shown, and by the difference in temperature between inside and outside air. The sum gives the loss of heat in B.t.u. by exposure then add to the foregoing as follows:

Ten per cent. for northern exposure and where the winds are to be counted on as an important factor.

Ten per cent. if heated day time only, and the location of the building is not exposed.

Twenty per cent. when the building is heated day time only, and the location of the building is exposed.

Thirty per cent. when the building is heated during winter months intermittently with long intervals of non-heating. —*From the "Ideal Fitter," compiled from well-known authorities.*

When the engineer's requisitions are not honored in full, it is time to get a new chief or a new man in the supply department. Trust a man or fire him.—*Marine Engineering.*

A Good Suggestion for All

Do you ride all the bumps or bumpers of the war news from day to day? Many good patriots do. Each morning brings its passing changes in the war situation; now gloom in the form of a setback on the western front, or further disintegration in Russia, or rumors of delay in our own war preparations. Next morning, like as not, there will be something of a hopeful nature, such as the checking of the Huns' drive in Italy, or a raid by the British or French, or good news here at home. To follow and feel all these glees and glooms from day to day is human and exciting. But it involves much useless wear and tear of the spirit. There is another viewpoint—that of disregarding the daily shifts and changes in the war situation, keeping one's attention concentrated on the long haul of war and the final result.

That haul is still a long one. For Germany is not beaten yet, but the results are sure, because we have right on our side, and also the largest battalions. If you grow warm and then cold, and alternate between enthusiasm and depression with the daily news changes, you not only waste your energy, but are likely to fluctuate in your policy as a business man and your determination as a patriot. The good resolution to save food, support Uncle Sam financially and cheerfully, adjust your business and habits to the war program will be stiffened on the morning that you read about some Hun atrocity against our own soldiers in France. But in a week there may be news of a different character, which leads you to let down a little, on the assumption that Germany has begun to crack and that the war is about over. It is good business, good patriotism and good conservation to forget most of the headlines in the morning paper and concentrate strictly upon the long, hard grind between today and the final result. That will save your spirit, buck up your resolution and enable you to do your utmost in winning the war.

Moreover, it will enable you to get out of the war, as a business man and a patriot, the utmost benefit from war adjustments. Those adjustments make for wiser and more economical personal habits, as well as a business grounded in sound economy. Even should peace come tomorrow, you can never go back to the old heedless wasteful ways either in business or livelihood. Don't ride the bumps of the war news!

Settle down in harness for the long grim haul that counts. —*James H. Collins, Editor "Weekly Bulletin."*

Modern Towers of Babel

One of the distinct hazards in employment in this country rests on the coworking of men of different nationalities who do not understand the language of one another, and the question has been frequently raised in the courts as to when an employer becomes liable for injury to one of his workmen caused by negligence of another who has not become "acclimated" to our language.

Very recently this question was presented to the New York Court of Appeals in the case of Barber vs. Smeallie, 117 Northeastern Reporter, 611, where a non-English speaking employee started a pump while a coemployee was known to him to be in a perilous position, resulting in injury to the latter. The injured man, in suing his employer, sought to fix liability under the rule of law that an employer is responsible for injuries inflicted by a fellow employee who was previously known to be so incompetent for the work assigned to him as to make the employer guilty of negligence in retaining him to the peril of other workmen. But the court, reversing judgment which had been awarded in the injured man's favor, decided that a worker cannot be said to be incompetent merely because he does not understand English, and that the employer cannot be held in such instances unless there was a direct and natural connection between his unfamiliarity with English and the accident. This unfamiliarity could not be said to be the cause of the accident in this case; the direct cause was mental deficiency of the negligent man, apart from his linguistic ignorance, and it was not claimed that the employer previously knew of that deficiency.

Personals

J. C. Halvey has resigned his position as master mechanic with the A. H. Crist Co., Cooperstown, N. Y., to accept a position with the Air Nitrates Corporation, and after spending some time studying the processes at Niagara Falls, he will proceed to Muscle Shoals, Ala.

Frederick D. Herbert, who has for years been identified with the marine industry and for the last ten years New York manager of the Terry Steam Turbine Co., has been elected president and general manager of the Kearfott Engineering Co., Inc. He will continue to handle the marine work of the Terry Steam Turbine Co., at 95 Liberty St., New York, which is the office of the Kearfott Engineering Co., Inc.

J. A. Kinkead, who has been the New York representative of the Parkesburgh (Penn.) Iron Co. for the past ten years, leaves shortly to locate in San Francisco to look after the interests of the same company and also the Chicago Railway Equipment Co. there. On finishing his course in the University of Illinois, Mr. Kinkead was employed as chief inspector of material for the Northwestern Railroad and later had general charge of the inspection of material for the American Locomotive Co. He is a well-known member of many technical and engineering societies and clubs.

Engineering Affairs

The Pennsylvania State Association of the N. A. S. E. will hold its annual convention at Chester, Penn., June 20, 21. Indications point to a successful meeting.

The Canadian Association of Stationary Engineers will hold its twenty-ninth annual convention at London, Ont., June 25-27. The meetings of the delegates and the display of the exhibitors will be held at Hymen's Hall, Queens Ave. and Clarence St. A hustling local committee assisted by G. C. Keith, Secretary of the Exhibitors' Association, are completing final arrangements.

The National District Heating Association will not hold its regular convention this year, but the executive committee, together with the chairmen of the standing committees, and as many members as possible, have decided to meet at the Breakers Hotel, Cedar Point, Ohio, July 8-9, to discuss various matters now affecting the heating companies and to receive reports of the standing committees for the year.

Miscellaneous News

Production of Coal was somewhat curtailed in the Charleston, (W. Va.) section last week operators of the mines claiming that a part of the loss of production was due to the failure of the Logan Power Co. to furnish sufficient current to them.

United States Fuel Administrator Garfield announced recently the appointment of John P. White, Labor Advisor to the Administration, as the representative of the Administration on the Labor Policy, of which Felix Frankfurter is chairman. It is the task of the Labor Policy Board to find out what the needs of labor are so that a labor budget can be made. The Government departments having industrial-service bureaus independent of each other have given rise to some confusion and waste, variations in wages leading workmen to leave one job for another. In one sense the Labor Policy Board will constitute a centralized employment agency for the United States.

Business Items

The H. W. Johns-Manville Co's. Houston (Tex.) office will be located at 424-426 Washington Ave. on and after July 1.

The Colonial Supply Co., Pittsburgh, Penn., because of its increasing business has purchased and moved into the building at 217 Water Street.

The A. Gulowsen A/S of Christiania, Norway, manufacturers of the "Grei" heavy oil engine, has incorporated the Gulowsen Grei Engine Co. at Seattle, Wash., and is erecting a large factory where these engines will be manufactured for supplying the American trade.

The Crane Packing Co.'s New Yory City office has moved to larger quarters in the Park Row Building, with Julian N. Walton as manager. A. W. Payne, for some time manager of this district, has been made sales manager of the United States and Canada, with headquarters at the home office in Chicago. The Pittsburgh offices are located in the May Building, the Philadelphia office in the Colonial Trust Building.

The Reeves Engineering Co., Trenton, N. J., has been incorporated to act in the capacity of constructing and efficiency engineers and to specialize in the design and construction of power and industrial plants. The business and assets of the Reeves-Cubberly Engine Co., Trenton, N. J., have been absorbed by the Reeves Engineering Co., which will continue the manufacture of the Reeves steam and gas engines.

Parr Terminals Co., Wilfred N. Ball. Engineer, 225 First National Bank, Oakland, Calif., wants catalogs and other data from manufacturers of materials or equipment used in the construction of piers, warehouses, industrial buildings, belt line railway and street work and cargo handling equipment; coal bunkering and handling equipment; floating drydock and marine railway equipment; general shipyard machinery and equipment.

Peerless No. 4810 Air Hose was used in a remarkable record at driving rivets made under handicap at the Morse Dry Dock and Repair Co.'s plant in South Brooklyn recently. Bertram Bieher, riveter, and his holder-on, Eddie Hesse, with four heater boys, drove 1480 regulation-size ⅞-in. button-head rivets in 4 hours and 10 minutes. For a record of this kind it is obvious that air hose plays an important part in rivet driving. It would not do to have to stop to make repairs.

Trade Catalogs

Monthly Stock List of Cutters.—The Cleveland Milling Machine Co., Cleveland, Ohio. Pp. 36; 3½ x 6 in.; illustrated.

The Stoker for the Higher Volatile Coals. Laclede-Christy Clay Products Co., St. Louis, Mo. Pp. 12; 8½ x 11 in.; illustrated.

Buffalo Forges. Buffalo Forge Co., Buffalo, N. Y. Pp. 111; 5 x 7½ in. Illustrating and describing complete line of portable and stationary forges.

Coxe Stoker. Combustion Engineering Corp., New York City. Bulletin Cl. Pp. 29; 6 x 9 in. Showing the application of the traveling grate idea. Copy free on request.

Zelnicker's Bulletins. Nos. 241 and 243. Walter A. Zelnicker Supply Co., St. Louis, Mo. Listing bargains in rails, cars, locomotives, general power-plant equipment and machinery.

Link-Belt Silent Chain. Link-Belt Co., Chicago, Ill. Book No. 312, Pp. 40; 6 x 9 in. Giving illustrations and reasons why the silent chain drive is the most efficient transmission for operating machine tools.

Pulverized Coal Equipment. Lehigh Car, Wheel and Axle Works, Catasauqua, Penn. Catalog No. 71. Pp. 28; 8 x 10½ in. Descriptions and illustrations of various units used for the production of pulverized coal attractively presented.

Skinner Automatic Engines. Skinner Engine Co., Erie, Penn. Pp. 47; 8½ x 11½ in. An attractive illustrated catalog devoted entirely to the exposition of single-valve center- and side-crank Skinner engines, in single-cylinder type from 50 to 600 hp.

Light for the Clothing Industry. Edison Lamp Works of the General Electric Co., Harrison, N. J. Bulletin No. 43,410 contains the latest information on the correct methods of lighting industrial plants. It is well illustrated, showing various lighting schemes most suitable for industrial purposes.

Wheeler-Balcke Cooling Towers. Wheeler Condenser and Engineering Co., Carteret, N. J. Bulletin 109-B. Pp. 28. Shows Wheeler-Balcke cooling towers of numerous designs in capacities varying from a few thousand gallons per hour to nearly a million gallons per hour. It is shown better, in some cases, to combine natural and forced draft. Two pages are devoted to Wheeler-Barnard forced draft cooling towers, which are at times found preferable to the Wheeler-Balcke. Wherever sufficient ground area is available, however, the Wheeler-Balcke is usually considered by consulting engineers as the standard natural-draft tower.

NEW CONSTRUCTION

Proposed Work

9.

Me., Waterville—The Lockwood Co. is having plans prepared by I. W. Jones, Arch., Milton, N. H., for the erection of a new hydroelectric power plant here.

Mass., Boston—The Bureau of Yards & Docks, Navy Dept., Wash., D. C., has received low bids for improvements to its power plant at the Navy Yard, here, from Rideout, Chandler & Joyce, 178 High St., $31,000 (180 days); W. G. Cornell Co., 923 12th St., Wash., D. C., $35,884 (100 days); Lynch & Woodward, 287 Atlantic Ave., $37,764 (100 days).

Mass., Wellesley—Wellesley College is having plans prepared by French & Hubbard, Engrs., 88 Pearl St., Boston, for the erection of a 35 x 45 ft. addition to the boiler house here.

Conn., Danielson—The Goodyear Cotton Mills, Inc., plans to build a brick power house and install steam turbine engines. Estimated cost, $100,000.

N. Y., Auburn—The Empire Gas and Electric Co. plans to issue $1,717,000 bonds; the proceeds will be used to improve and extend its system. H. S. Coleman, Geneva, Gen. Mgr.

N. Y., Buffalo—The Buffalo General Electric Co., 206 Electric Bldg., has had plans prepared for the erection of a 1-story, 95 x 106 ft. sub station addition to its plant. Estimated cost, $17,000.

N. Y., Ossining—The Commission of New Prisons, Hall of Records, New York City, will receive bids for the erection of 5 buildings at Sing Sing; heat and power systems will be installed underground in tunnel. Machinery includes two 400 hp. boilers, piping, 25 hp. motors, etc.

N. Y., Otisco—The Otisco Light and Power Co. has petitioned the Public Service Commission for authority to build and operate an electric lighting plant.

N. Y., Warsaw—The Warsaw Elevator Co. has had plans prepared for repairs to its 1-story power house. C. E. Ketchum, Pres.

N. J., Newark—The Board of Education will soon award the contract for the installation of heating and power in the proposed Hawkins St. School.

N. J. Ogdensburg—The Wharton Steel Co. plans to rebuild its boiler plant at the limestone quarry which was recently destroyed by fire.

Penn., Enola—The Pennsylvania R. R. plans to improve and alter its power plant and engine house here. A. C. Shand, Broad St. Station, Philadelphia, Ch. Engr.

Penn., Meadville—The Northwestern Electric Service Co. plans to build an electric transmission line from here to Kearsage. A. E. Rickards, Commerce Bldg., Erie, Mgr.

Penn., Philadelphia—The Mifflin Chemical Corporation, Delaware and Tasker St., has had plans prepared for the erection of an addition to its boiler plant.

Wash., D. C.—The Bureau of Yards & Docks, Navy Dept., Wash., D. C., has received low bids for the construction of an electric duct system between the Navy Yard, here and the Capitol Power plant at Garfield Park (a) work complete (b) work complete according to bidder's plans and specifications, from N. W. Ryan, New York City, (a) $14,904 (60 days); G. M. Gest, 1330 Woolworth Bldg., New York City (a) $16,500 (75 days); F. S. Smith, 612 14th St., (a) $28,643 (60 days).

Wash., D. C.—The Bureau of Yards and Docks, Navy Dept., plans to build a power house at St. Juliens Creek, Va.; Specification No. 3072. Estimated cost, $7500.

Va., Norfolk—The Bureau of Yards and Docks, Navy Dept., Wash., D. C., will soon award the contract for the installation of an electric lighting and power system in shipbuilding slip No. 1. Estimated cost, $15,000. Noted May 28.

W. Va., Mannington—The Rachel Coal Co. plans to rebuild its power house, ventilation system, etc., at its mine.

N. C., Henderson—The Henderson Box and Lumber Co. plans to install a 150 hp. boiler, engines and a 150 kw. direct connected generator.

Tenn., Ripley—The Ripley Oil Mills is in the market for a second-hand 20 x 42 in. left-hand, rope-drive Corliss engine and also a 75 hp. crude-oil engine.

Tenn., Rockwood—The Public Light and Power Co., Chattanooga, plans to rebuild transmission line from here to Lenoir City. W. R. Stern, Winchester, Mgr.

Tenn., Spring City—Dayton Light and Power Co. plans to build transmission line from here to Dayton.

Ky., Fulton—A. S. Baldwin, Chief Engr. of Illinois Central R. R., 135 East 11th St., Chicago, will soon award the contract for the erection of various units here, including a 40 x 150 ft. boiler house; two 150 hp. boilers, one 85 ft. electric turntable, etc., will be installed. Total cost, $225,000.

Ky., Whitesburg—The Elkhorn Superior Block Coal Co has increased its capital stock from $35,000 to $100,000; the proceeds will be used to install new electrical machinery.

Ohio, Canton—The Canton Gas and Electric Co. has petitioned the State Public Utilities Commission for authority to build a high tension transmission line along the right of way of the Chicago, Burlington and Quincy R. R.

Ohio, Cleveland—The National Woolen Co. is having plans prepared by A. Gairing, Arch., for the erection of a 2-story power plant. H. W. Stecher, 3131 West 53rd St., Pres.

Ohio, Creeksville—The Central Power Co. plans to build a transmission line from here to Bearfield Twp E. T. Wagenhals, Newark, Supt.

Ohio, Fremont—The City Council is considering the installation of a gas and electric lighting plant to be erected here.

Ohio, Norwood—City will sell bonds for improvements and extensions to its electric lighting and water works systems. W. R. Suhr, Auditor.

Mich., Homer—The Homer Electric Light and Power Co. plans to build additions to its plant. G. H. Rising, Engr.

Ill., Amboy—A. S. Baldwin, Chief Engr., of the Illinois Central R. R., 135 East 11th St., Chicago, will soon award the contract for the erection of various units here, including a 40 x 150 ft. boiler house, etc.; two 150 hp. boilers, one 85 ft. electric turntable, etc., will he installed. Total cost, $250,000.

Ill., Carbondale—A. S. Baldwin, Chief Engr. of Illinois Central R. R., 135 East 11th St., Chicago, will soon award the contract for the erection of various units here, including a 40 x 150 ft. boiler house, two 150 hp. boilers, one 85 ft. electric turntable, etc., will be installed. Total cost, $250,000.

Ill., Jacksonville—City plans to vote on bond issue to build a dam, control station, etc. About $75,000. S. Greeley, 64 West Randolph St., Chicago, Engr.

Ill., Mounds—A. S. Baldwin, Chief Engr. of the Illinois Central R. R., 135 East 11th St., Chicago, will soon award the contract for the erection of various units including an addition to the boiler house; two 150 hp. boilers, one 85 ft. electric turntable, etc., will be installed Total cost, $250,000.

Wis., Wausau—City plans to establish a central lighting and heating plant here.

Iowa, Neola—City plans to improve its electric lighting and power plant. Estimated cost, $16,000.

Iowa, Sioux City—The Midland Packing Co. plans to build a boiler and power plant in connection with its proposed packing plant. Gardner & Lindberg, 140 South Dearborn St., Chicago, Engr.

Minn., St. Paul—The Northern Pacific Mutual Beneficial Association is having plans prepared for the erection of a hospital and power plant. Total cost, $300,000. H. S. Smith, 203 Railroad Bldg., Pres. L. Bassindale, Capital Bank Bldg., Arch.

S. D., Bradley—Dakota Northern Power Co. plans to build a power station. E. H. Lewis, Secy.

Mo., Maysville—City has plans under consideration for improvements to its electric lighting plant.

Okla., Miami—The Luck Jenny Mining Co. will build a concentration plant at its mine in Hockerville. Equipment including engines, boilers, etc., will be installed. Estimated cost, $60,000. W. F. Cooper., Supt.

Utah, Salt Lake City—Salt Lake Co. will soon award the contract for the installation of a heating system in the courthouse. S. G. Clark, Clerk.

Nev., Palisade—The Union Mines Co. plans to install a large quantity of electric machinery in its proposed concentrating plant.

Ariz., Kingman—The Schuylkill Mining Co. plans to install a power plant in connection with its milling plant now under construction.

Ariz., Phoenix—The State Hospital for the Insane has had plans prepared for the erection of a power house. Noted Apr. 16

Wash., Bellingham—The Boundary Red Mountain Mine plans to rebuild its power plant which was recently destroyed by fire.

Calif., Lompoc—The Lompoc Light and Power Co. plans to improve its plant and distribution system. Estimated cost, between $5000 and $10,000. A. H. Wishon, Fresno, Mgr.

Calif., Los Angeles—The California Edison Co. has been granted a franchise by the Board of Supervisors, for the erection and maintenance of an electric distributing system in Los Angeles County.

Sask., Lloydminster—W. and E. Johnson plan to build an electric lighting plant. Estimated cost, $60,000.

CONTRACTS AWARDED

R. I., Lonsdale—The Lonsdale Co. has awarded the contract for the erection of a transformer station, to The J. W. Bishop Co., 109 Foster St., Worcester, Mass.

N. Y., Albany—H. A. Biggs, Commissioner of Health, has awarded the contract for the installation of a heating system to the Merrill Co., 19 Pearl St., Boston, Mass., $45,082; the electric lighting system, to Gagen & Butler, Inc., 1402 Bway., New York City, $10,484. Noted Apr. 9.

N. J., Jersey City—The Elks Club Association has awarded the contract for the installation of lighting and power for its building on Hudson Blvd., to L. Fort, 428 Hoboken Ave. Estimated cost, $9000.

Ohio, Columbus—The Smith Agricultural Chemical Co., Champion and Leonard Sts., has awarded the contract for the erection of an addition to its power house, to the Frankenburg Constr. Co., 705 Columbus Business Savings and Trust Bldg.

Ohio, North Canton—The Hoover Station Sweeper Co., c o H. W. Hoover, has awarded the contract for the erection of a 1-story, 40 x 50 ft. addition to its boiler house, to Custer Bros., 141 Smith Ave., N. W. Canton. Estimated cost, $8000.

Mich., Cheboygan—The Cheboygan Electric Light and Power Co. has awarded the contract for the erection of a new power house at the Black River dam, to W. Moody, Cheboygan.

Mich., Detroit—The D. Stott Flour Mills Co., Warren and Grand River Ave., has awarded the contract for the erection of a 1-story, 35 x 50 ft. boiler house, to the Wisconsin Bridge and Iron Co., 1362 Penobscot Bldg. Estimated cost, $10,000.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular Current	Individual Current
Buckwheat	$4.60	$7.10—7.35
Rice	4.10	6.65—6.90
Boiler	3.90	....
Barley	3.60	6.15—6.40

BITUMINOUS

Bituminous not on market.

Pocohontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.00 a year ago.

*All-rail to Boston is $2.60. †Water coal

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* are as follows:

ANTHRACITE

	Circular Current	Individual Current
Pea	$4.90	$5 65
Buckwheat	4.45@5.15	4.80@5.50
Barley	3.40@3.65	3.80@4.50
Rice	3.90@4.10	3.00@4.00
Boiler	3.65@3.90	....

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Gross	Mine Price Net	Gross
Central Pennsylvania	$5.06	$3.05	$3.41
Maryland—			
Mine-run	4.84	2.85	3.19
Prepared	5.06	5.05	3.41
Screenings	4.50	2.55	2.85

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty, Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The ratte to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Current	One Yr. Ago	Current	One Yr. Ago
Pea	$3.45	$3.00	$4.35	$3.90
Barley	2.15	1.50	2.40	1.75
Buckwheat	3.15	2.50	3.75	3.40
Rice	2.65	2.00	3.65	3.00
Boiler	2.45	1.80	3.55	2.90

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes	$2.55—2.70	$3.25—3.40
Mine-run	2.35—2.50	3.00—3.15
Screenings	2.05—2.20	2.75—2.90

St. Louis—Prices per net ton f.o.b. mines are as follows:

	Williamson and Franklin Counties	Mt. Olive & Staunton	Standard
6-in. lump	$2.55-2.90	$2.55-2.70	$2.55-2.70
2-in. lump	2.55-2.90	2.55-2.70	2.55-2.70
Steam egg	....	....	2.20-2.40
Mine-run	....	2.35-2.50	2.00-2.20
No. 1 nut	2.55-2.90	2.55-2.70	....
2-in. screen	2.05-2.20	2.05-2.20	....
No. 5 washed	2.05-2.20	2.05-2.20	....

Birmingham—Current prices per net ton f.o.b. mines are as follows:

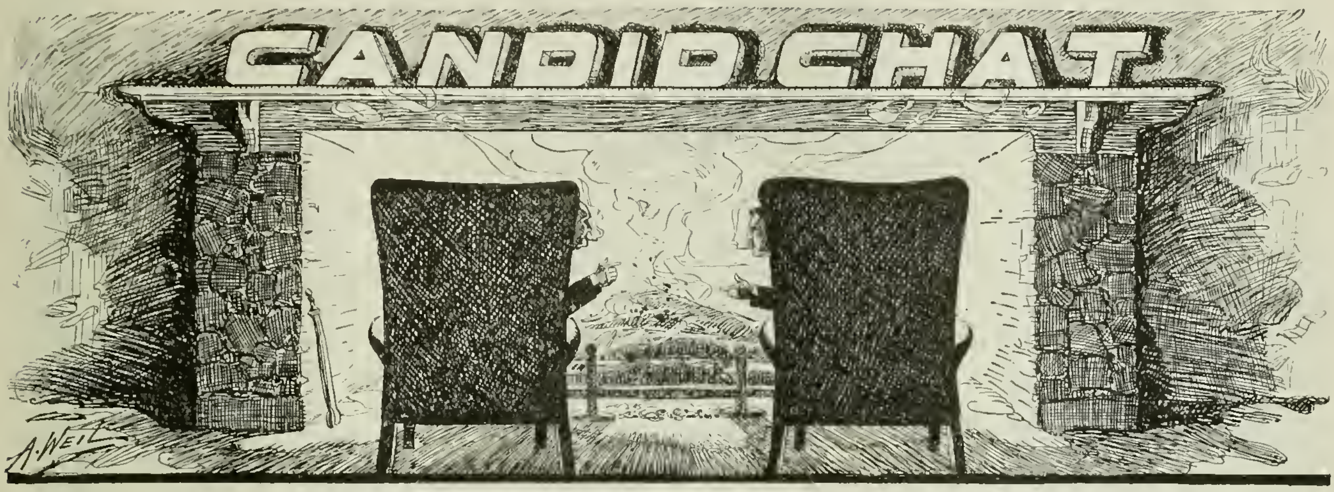
	Mine-Run	Lump & Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona	2.15	2.40	1.90
Black Creek, Cababa.	2.40	2.65	2.15

Government figures.

Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

POWER

Vol. 47 NEW YORK, JUNE 18, 1918 No. 25



Confidence in Employers

IT is the confidence which even the humblest worker has in his employers and the product he helps to make that goes toward general success. Too often we see and hear of engineers and others in power-plant work who lack confidence in their employers.

For instance, an engineer wants some new appliance, a new piece of apparatus or some supplies. He wants them immediately whether they are of great necessity or not. Well, perhaps owing to expenditures in other lines or departments, the firm is not in a position to buy these things just at the time the engineer wants them.

As a result, the engineer loses confidence in his employers—not that the loss of confidence is deserved, for generally the engineer views only one side and that is his. He finally decides that the firm is too cheap to lay out a few dollars, so what is the use of trying to do things. He neglects what old apparatus he has—to his own undoing.

An engineer had a cold-water pump in his plant, drawing water from a deep well and pumping to a high pressure. The pump was not placed in a very suitable position—it was exposed to all sorts of dirt and grit. Of course it was running under hard service, and with a little extra care could have been made to hold out awhile longer. Instead, the engineer wanted a new pump and a larger one. He could not get one, so he made up his mind that the firm was too cheap a firm for him to work for, and he quit. The new engineer came and gave a lot of time and patience to the old pump, and it was not very long before he had a nice increase in salary, besides getting just the pump he wanted.

Engineers, realize that there are other expenses in an isolated plant besides the power house, and your employer has to meet them all. Let your employers see that you have full confidence in what they are doing, and they will surely place confidence in you.

Contributed by J. C. Halvey, Cooperstown, N. Y.

FIG. 1. INTERIOR VIEW OF THE PRESENT BADEN STATION BOILER ROOM

Remodeling the St. Louis Baden Station

By K. TOENSFELDT

The remodeled station will contain four boilers from an old station and four new boilers of the same type and size, making a total of 3300 boiler horsepower. Chain-grate stokers will be used. The total investment will be $177,500, and it is estimated that the yearly saving in operating expenses will be about $11,797.

THE Baden Station or High-Service Station No. 3 is situated in the northernmost part of the City of St. Louis and was built in 1896. The growth of the city westward, leading farther from the original pumping station and into the higher parts of the surrounding country, necessitated additional pumping capacity and a higher main pressure. The Baden Station, the water mains from which in general circumscribe the older central or downtown parts of the city and supply the outlying western, southern and the higher districts, pumps a pressure of 125 lb. into a closed system. The high-service stations Nos. 1 and 2, supply the central and lower districts and pump against a pressure of 85 pounds.

The high-service stations Nos. 1 and 2, and the low-service station No. 2 have been reconstructed with modern equipment and were completed during the summer of 1916, and in the fall of last year an ordinance was passed appropriating funds for the reconstruction of the Baden Station. Although the present time is most inopportune for such an undertaking, the physical condition of the plant is such that the change is a necessary one. Fortunately, the Water Division is able to make use of much of the equipment from another station where the equipment of two engine houses was connected to the boilers of one remodeled boiler room, leaving the machinery of the abandoned boiler room available.

In the engine room there is little to be done. The six original vertical, triple-expansion pumps are in good condition, some revealing better duties on recent tests than were obtained on the acceptance tests. The remodeling of the engine room will merely involve the installation of a single new 10-in. steam header and loop to replace the present three 10-in. mains. The renewal of these is necessitated by the anticipation of using higher steam temperatures, which mean the use of heavier cast-steel valves and fittings in place of the present light cast-iron ones.

There will be a resultant saving in the engine room due to the use of superheated steam in the pumps and a saving in radiation loss due to the single header replacing the three present headers. A series of tests were made on pump No. 13 at the high-service station No. 2 to determine the saving effected by superheating. Fig. 3 shows the results graphically.

It is of interest to mention that superheated steam has caused cracks of destructive extent in the old unannealed high-pressure cylinder heads of the pumping engines at the high-service station No. 1. These were renewed with new annealed heads with properly proportioned reinforcing ribs.

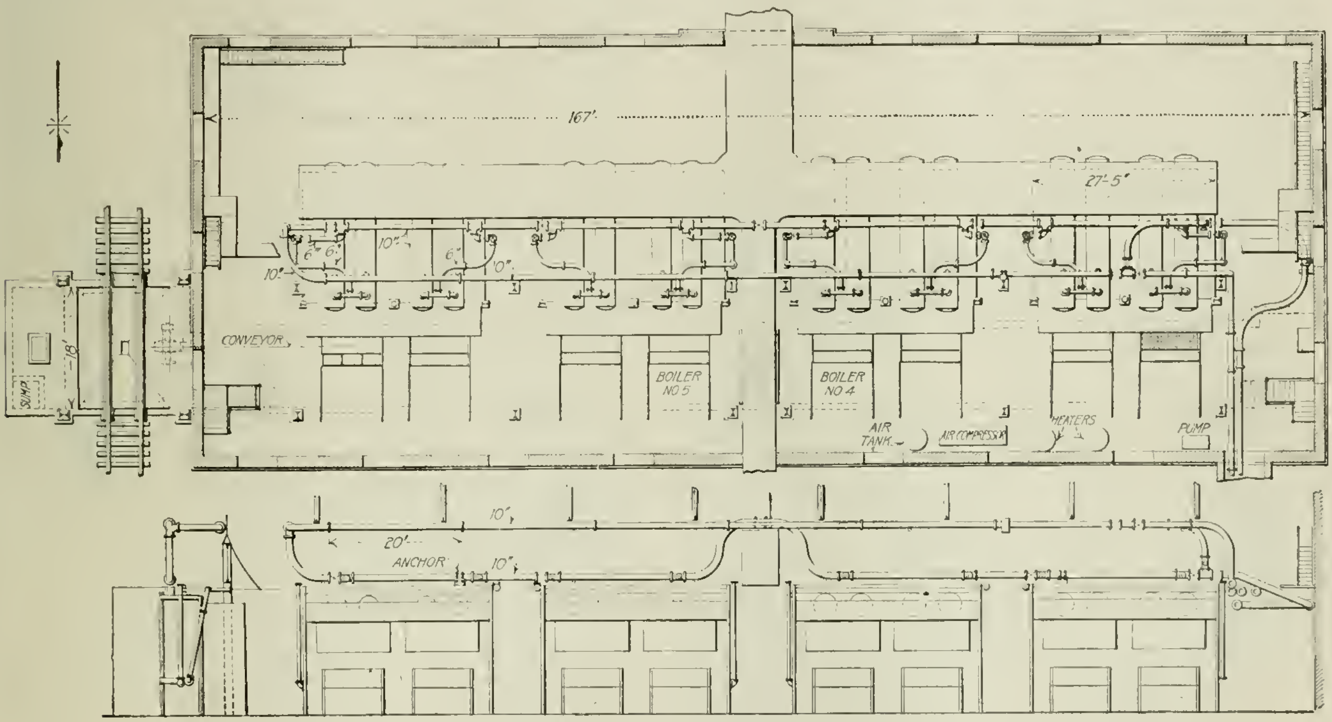


FIG. 2. PLAN AND ELEVATION OF THE NEW BADEN STATION BOILER ROOM

The boiler room of this station was completed in 1898. The equipment consist of four batteries of two each, or eight 277-hp. water-tube boilers each of which is equipped with down-draft type of furnaces. The boiler plant at present is well taxed to its capacity during periods of maximum pumping, and is in immediate need of enlargement. The boilers are in their twentieth year of service, having done duty practically continuously day and night, and they have already been running longer than what is considered the usual life of boilers of this type. In Fig. 1 is shown an interior of the present boiler room and indicates the attendant requirements in man-power with these old-type hand-fired boilers for handling coal and ashes. The tube spacing of the down-draft furnaces is such that the large-sized coals must be bought for fuel.

The following is taken from the annual report of 1917 and shows the saving that can be effected by remodeling the boiler plant, based on the actual operating and coal costs for the year 1916-17:

Total coal burned, tons	22,750
Cost of egg coal unloaded at $1.65 per ton	$37,537
16 firemen at $90 per month	17,280
16 coal passers at $65 per month	12,480
1 boiler-room foreman at $75 per month	900
1 boiler washer at $90 per month	1,080
Total	$69,277
Cost per 10,000 lb. of steam	$0 24
Total water evaporated, lb	288,000,000
Cost of proposed new tunnel	$10,000
Cost of proposed new bunker, coal and ash-handling equipment	60,000
Cost of four new 400-hp. boilers	35,200
Cost of four new superheaters	7,500
Cost of moving four 400-hp. boilers from Bissell's Point to Baden	3,200
Cost of brick settings for eight boilers	9,600
Cost of stokers for eight boilers	16,000
Changes in steam headers and feed lines	3,000
Cost of new breeching	5,000
Cost of proposed new stack	28,000
Total investment	$177,500

To evaporate 288,000,000 lb. of water with screenings containing 10,000 B.t.u. per lb. would require

$$\frac{288{,}000{,}000 \times 970 \times 1.07}{10{,}000 \times 0.65} = 46{,}000{,}000\ lb.$$

where 1.07 = factor of evaporation and 0.65 = efficiency. Hence with the new equipment we would have

Total coal burned, tons	23,000
Price per ton	$1 35
Cost of screenings	$31,050
6 firemen at $90 per month	6,480
8 coal passers at $65 per month	6,240
1 boiler-room fireman at $75 per month	900
2 boiler washers at $90 per month	2,160
Interest on investment at 6 per cent	10,650
Total cost to generate steam	$57,480
Cost per 1,000 lb. steam	$0 199
Yearly saving possible	$11,797

This represents a saving on the investment ($177,500) of 6.6 per cent. even during these times of high prices.

It may be of interest to relate some of the symptoms of age in the boilers. Each unit has two 36-in. drums which were originally of material $\frac{5}{16}$ in. thick with longitudinal, triple-riveted lap joints. The old tubes are requiring continual renewal, as hydrostatic tests to 150 lb. after turbining, invariably reveal leaks, with the consequent removal of from two to eight tubes. These tubes, when cut to pieces, have commonly shown weak spots. During the last year a tube rupture which occurred in the sixth bank caused a temporary shutdown of the entire station. If it were not for the immediate reconstruction of the plant the boilers would all have to be retubed.

The plant will furnish steam at 150 lb. pressure and 150 deg. superheat. The type and size of new boilers determined upon for the remodeled Baden station was governed by the water-tube boilers that were removed from the high-service station No. 1, due to connecting the engines of this station to the boilers of the high-service station No. 2, as already mentioned. These boilers, four in number, are in good condition, each of 410 hp. capacity, and will be dismantled and reinstalled together with their superheaters at the Baden station. In order to maintain uniformity of parts throughout the boiler room, four new boilers of the same type and size will be added. The total plant capacity will be 3300 boiler horsepower which, it is estimated, will serve the pumping demands for the life of the boilers.

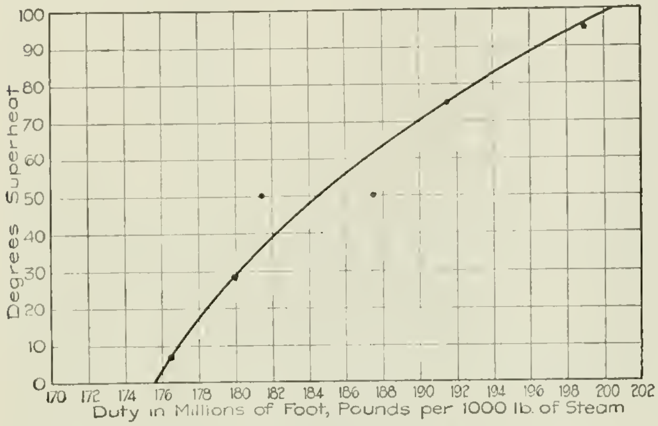

FIG. 3. CURVE SHOWING THE RESULT OF TESTS

The boilers will be fired by chain-grate stokers with a ratio of boiler-heating surface to grate area of 48. This ratio, with a properly designed furnace, will drive the boiler efficiently at below rating and at 30 per cent. and more over capacity. The chain-grate stoker was selected as being best adapted for the purpose, considering the extent and nature of the load, the grade of coal to be burned and the amount of money invested. The daily peak of the maximum pumping periods at this plant, which pumps into a closed system, varies about from 1.1 to 1.3 of the average and from 1.2 to 2.0 of the minimum. The chain-grate stoker meets these load demands nicely, and it was considered unwise to go into a more costly and elaborate type of stoker with all attendant auxiliaries, especially in a water-works boiler plant where the reserve capacity in the equipment is larger than in most commercial plants.

The question of installing an economizer was also considered, and although a fair return on the investment might be realized, over the life of the economizer, yet with the present load and cost of economizers, and for a few years to come, it was questionable whether any gain would be realized. Provision has been made, however, in the planning of the boiler plant and in the breeching, should occasion arise in the future for the installation of economizers.

Fig. 2 shows a plan of the boiler room. Coal is dumped from the railway track into the track hopper, passes through a crusher and reciprocating feeder into a continuous pivoted bucket conveyor, which elevates it and dumps it, with the aid of a traveling tripper, into the desired bunker. The same conveyor receives the ashes from the boilers and delivers them to the ash hopper over the track hopper. Ashes may be deflected through a chute to a car on the side track or may be stored in the hopper. A conveyor of the same type, handling both coal and ashes, has been in service at the low-service station No. 2 for three years, and no appreciable wear due to handling ashes in the same conveyor has been noticed. The storage capacity of the bunkers was made as large as possible, this feature having manifested itself as very desirable during the past winter.

Fig. 4 shows a transverse section through a boiler setting. Coal may feed from the bunker through automatic weighing scales into the stoker hopper, or it may be shunted by means of a long spout (with the scales pushed aside) from the bunker past the stoker hopper into the siftings hopper and down onto the conveyor, whence it may be elevated and dumped into another hopper.

All coal is weighed as used, and the boiler-feed water is measured by a venturi meter with integrating and indicating recorders. A weekly efficiency record showing the relative station performances is bulletined at all stations. Each boiler is equipped with indicating steam-flow meter and CO_2 apparatus. Stack-breeching temperatures are recorded on a continuous chart.

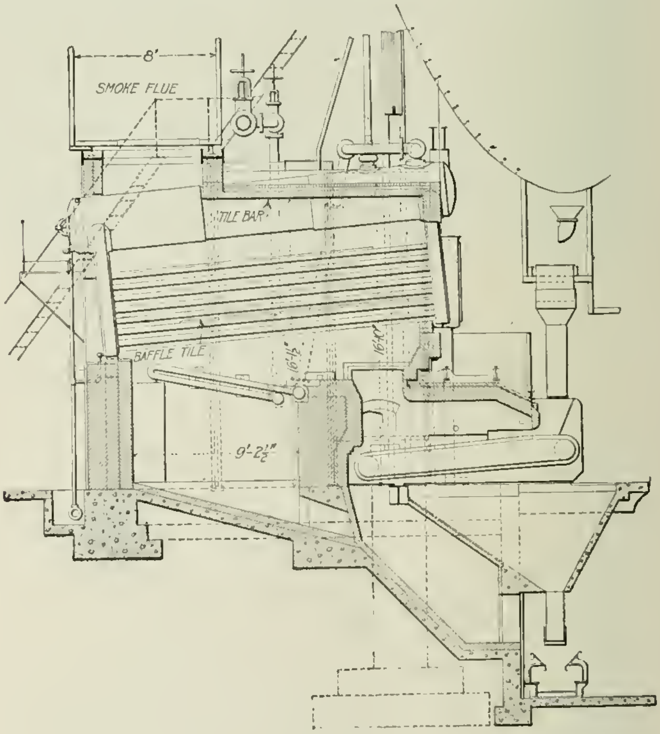

FIG. 4. SECTION THROUGH ONE OF THE BOILERS AND SETTING

The steam piping was designed on the loop plan so that both in the engine and boiler rooms there will be two ways of getting steam to the engines or from the boilers. Fig. 2 shows the piping in the new boiler room in both plan and elevation. The maximum velocity in the 10-in. header alone will approximate 7600 ft. per minute. All valves and fittings will be of extra-heavy cast steel with all joints male and female faced.

A new reinforced brick-veneer smoke-stack, 235 ft. high and 9 ft. 6 in. mean diameter, will maintain a 1 in. draft at the breeching of the farthest boiler. The design was treated to conform with the style of the architecture of the station buildings.

During the reconstruction of the station the service must be uninterrupted, and for this reason the new boilers face opposite to the present ones. This permits the new breeching and stack to be erected while the old boilers are in service and throws the major part of reconstruction work out of the way of the firing aisle of the old boilers.

It is expected to have the Baden station well toward completion by the summer of 1919.

Some Characteristics of Babbitt Alloys

The melting point of both genuine babbitt and strictly lead-base babbitt is around 500 deg. F., and this is about as high a melting point as can be obtained in a babbitt alloy. The melting point of a babbitt is always lower than the arithmetical mean of the melting points of the metals forming the compositions, and variations from certain rules in mixing reduces the melting point of the mixture below that of the most fusible metal in the alloy.

As an illustration, take a mixture of 87 per cent. lead and 13 per cent. antimony. Since the melting point of lead is 619 deg. and of antimony 834 deg. F., it would be natural to suppose that adding antimony to lead would bring the mixture to a higher melting point than that of lead, say to the mean melting point of the two, about 645 deg. F. At any rate, it would not be unreasonable to expect to obtain a higher melting point than that of lead (619), but as a matter of fact the melting point of this alloy is 477 deg. F. This is the lowest melting point of the series of lead and antimony mixtures.

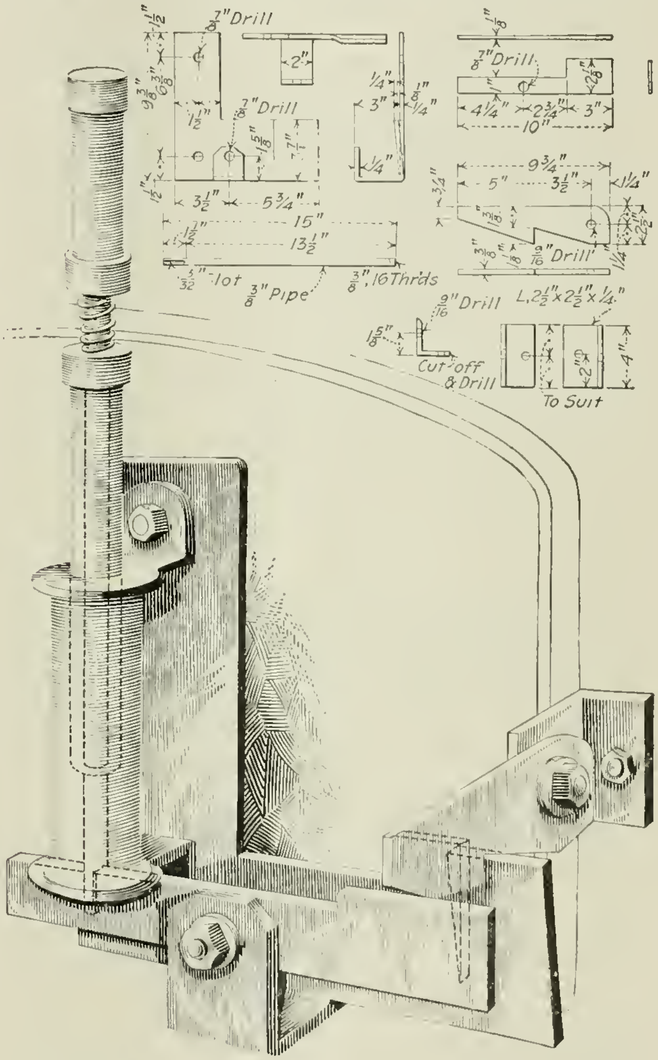
A tin and lead mixture consisting of about 60 per cent. tin and 40 per cent. lead melts at about 336 deg. F., representing the low limit, while another of about 60 per cent. lead and 40 per cent. tin melts at about 412 deg. F., representing the high limit. This latter mixture is known commercially as "wiping solder" and is used for that purpose by plumbers because it remains in a pasty stage while cooling through a range of 70 deg. F.

There is, however, a widespread belief that the cost of a tin-base babbitt can be cheapened without injury to its quality by the addition of lead, and also that the quality of a lead-base metal can be improved by increasing the tin content—this latter idea being based no doubt on the assumption that if a little tin is good more is better. But without knowledge of the effect produced in alloying certain kinds and proportions of metals, it is an easy matter to fall into grave error in compounding babbitts. Intermediate grades of babbitts have their use, but they can only be used successfully under most favorable conditions, and they generally fail under heavy pressure, high speed and scant lubrication, chiefly because of their low fusibility, which makes them highly susceptible to the influence of frictional or initial heat. As far as outer appearances go these intermediate grades seem to be most desirable, and they will also stand the usual physical tests of hammering, cutting and bending; but when put in service, they are apt to give trouble. This is generally attributed to some mechanical defect or to the lubrication, as users are in the dark as to other possible causes, the chief one being the low melting point, influenced, as shown, by the mixtures.

Safety Latch for Furnace Door

By C. W. Howard

The illustration shows a safety latch for boiler-furnace doors, which I designed and put on the Heine boilers of the Celina (Ohio) Municipal Electric-Light and Water-Works plant. These latches have been in continued use for two years, and in that time have given no trouble and have required no repairs. The parts are shown in sufficient detail, with dimensions, to permit anyone to order or construct others from them.



GENERAL VIEW AND DETAILS OF SAFETY LATCH

The object, of course, is to provide a latch that will hold the door closed and prevent the fire from being blown out into the fireroom in case of a tube failure, and at the same time one that is not cumbersome to manipulate. This device, I believe, meets these requirements and is at the same time inexpensive to make. A slight pressure on the handle above the spring raises the latch so that the door can swing open.

Interpreting Steam-Turbine Test Curves

By H. E. BRELSFORD

A brief description of standard turbine data curves, and how they are derived and used in interpreting turbine characteristics is given.

THE following curves are all based on a constant number of jets or nozzles in operation. Fig. 1, a power-pressure curve, is plotted to show the increase of power with increase of pressure at a constant speed (approximately so, varying only with governor regulation). Used simply as an indication of the turbine's power capacity, this curve shows the maximum power of the turbine. As the initial steam pressure is generally a fixed quantity, the maximum ring pressure is determined, hence the horsepower at this pressure is determined. This horsepower may be increased or diminished by using larger or smaller nozzle areas, and of course using more or less steam proportionally. Ring pressure may be defined as the pressure existing on the first set of nozzles and it is controlled by the governor. With a given speed it takes a certain amount of pressure to run the turbine at no load. This readily shows that with atmospheric exhaust the power-pressure line will not pass through the 0 gage-pressure point. As a general case this may be stated in this way: When the power-pressure line is plotted, the point at which it intersects the pressure line will be at a pressure greater than the exhaust pressure, the magnitude of the difference representing the sum of the no-load or rotation and radiation losses in the turbine. This form of curve is valuable as it may be used as a chart to show the horsepower being developed by the turbine at any given ring pressure while in operation. This curve is, of course, determined experimentally by an actual test and is a straight line.

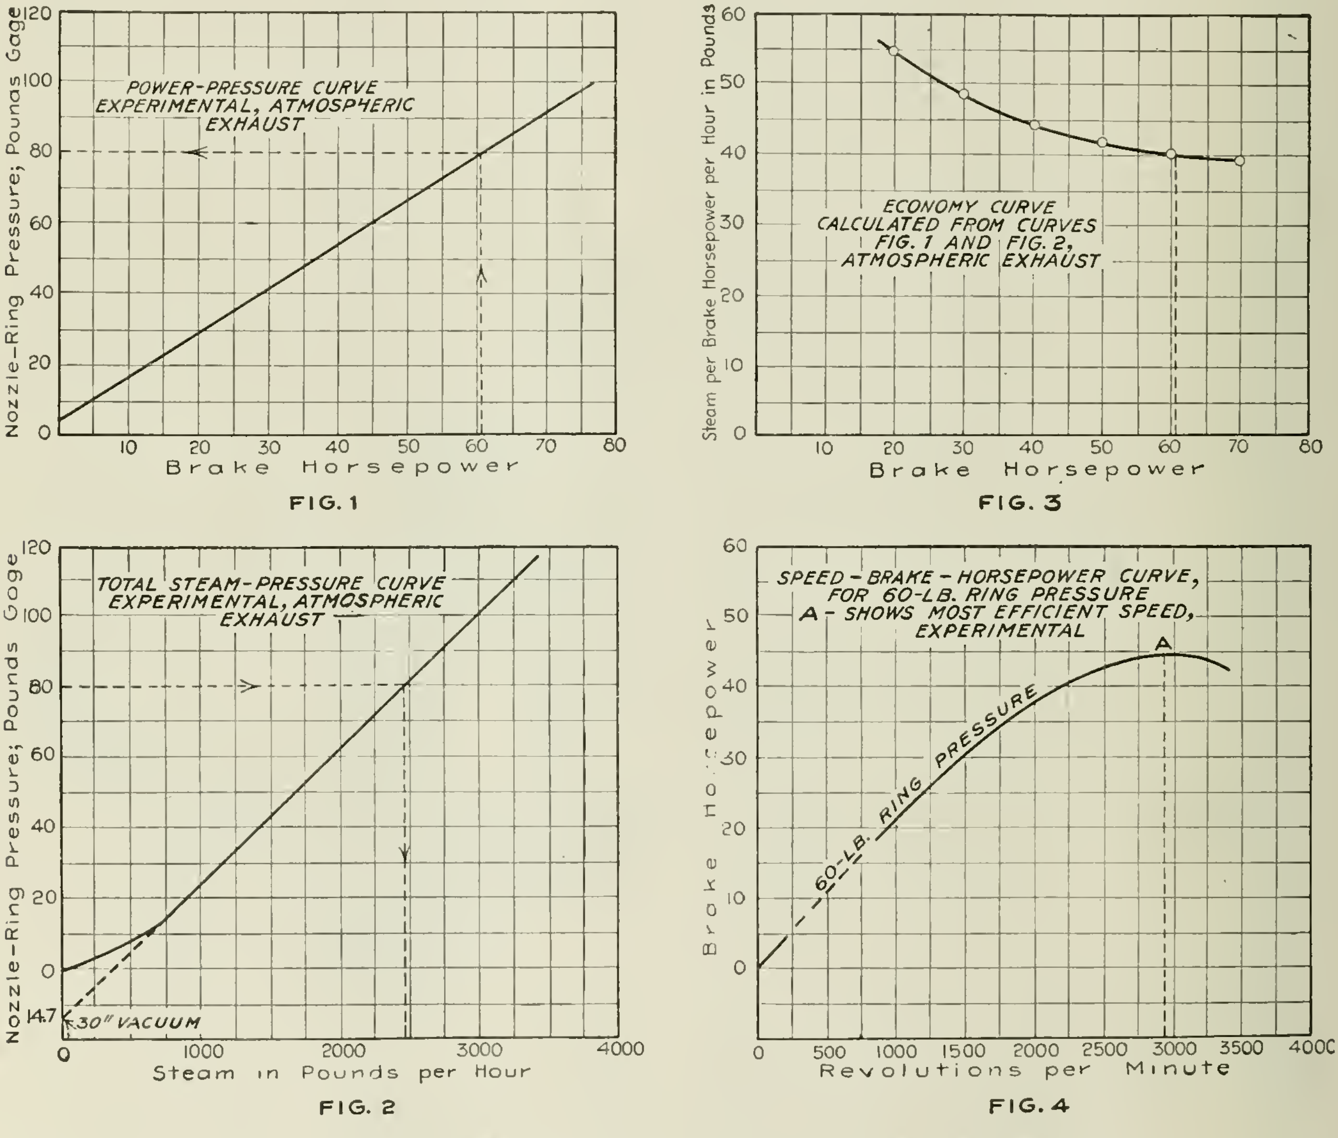


FIG. 1

FIG. 3

FIG. 2

FIG. 4

FIGS. 1 TO 4. CURVES SHOWING DIFFERENT CHARACTERISTICS OF STEAM TURBINES

Fig. 2, a steam-flow-pressure curve, is plotted to show the rate of flow of steam with any pressure. This curve is also a straight line except in the region where the absolute exhaust pressure (back pressure on the jets) is less than 58 per cent. of the absolute nozzle-ring pressure (initial pressure on the jets). In a single-stage turbine or a single-element Curtis turbine with atmospheric exhaust, with jets discharging into atmosphere, the initial pressure must be more than 10.63 lb. gage or the points on this power-pressure curve will not be in a straight line. A multi-stage turbine has the same characteristic straight-line pressure curve, but here the break is determined by the relation of the ring pressure to the pressure in the first stage. There is hardly a perceptible difference, however, from the straight single-stage turbine. On a multi-stage turbine the exhaust pressure can be carried through a very considerable range before altering the steam-flow rate.

With any nondiverging nozzles the steam flow per hour is calculated from the formula

$$W = \frac{SA}{0.04V}$$

where

W = Pounds steam per hour;
S = Velocity in feet per second of steam issuing from the nozzle;
A = Area of nozzle throat (also mouth) in square inches;
V = Specific volume of steam at the pressure into which the jet discharges;
0.04 = A constant which takes into account the time and space factors of the different quantities.

It will thus be seen that on a multi-stage turbine if the exhaust pressure is increased it raises the back pressure against each set of jets or nozzles. Each stage then can be considered as an individual single-stage turbine, and its characteristic pressure-flow line would be identical with the first case discussed. It should be noted, though, that the ratio of back pressure to initial pressure on the last stage, and hence the ratio of specific volume to velocity, is slightly different from the ratio of first-stage pressure to ring pressure. The lower end of a flow curve is, however, not of any consequence, as the real operating conditions are always at least above quarter load.

The curve, Fig. 2, at the lower end shows where the line curves to the left and passes through 0 gage pressure. If this curve was plotted to absolute pressures, it would pass through absolute-zero pressure the same as if the straight portion is produced in Fig. 2. If plotted to gage pressure the straight part produced will pass through absolute zero the same as when plotted to absolute pressure, 14.7 below zero gage. If the throat area of an expanding nozzle is known, this curve can be computed according to Napier's formula, but ordinarily it is determined by test and this serves as a check on nozzle or jet dimensions. One point determines this line, as it can be drawn through absolute zero and the given point. It is also an interesting fact that the steam flow is independent of the speed as far as can be determined in commercial testing. This fact makes it possible to make a steam-flow test with the turbine's rotor locked so that it cannot rotate. There is, however, a small difference existing, theoretically, due to the reheating effect of the greater relative velocity between the steam and the blading.

An economy, or brake-horsepower-water-rate curve, is given in Fig. 3 and is plotted to show the variation of the economy or steam rate with the output at constant speed. It is, of course, a well-known fact that the economy at partial loads is not as good as at full load, or at the load for which the turbine was designed to operate with best economy. An economy curve will therefore show an improvement with increase of load, the speed remaining constant, until a point is reached where the quantity of steam is the maximum for which the turbine was designed, and then the rate per horsepower will usually increase. This curve is derived directly from curves 1 and 2. For instance, if it is desired to determine how much steam is required per horsepower-hour when the output is 60.75 hp.: Then on curve 1 at 60.75-hp. pass vertically to the power line and from the intersection pass horizontally to the pressure line and read the pressure required to produce 60.75 hp. On curve 2 at this same pressure, 80 lb., pass horizontally to the flow line and at the intersection drop straight down and read the quantity of steam flowing at this pressure, namely, 2460 lb. per hour. This value divided by the brake horsepower gives the pounds per brake-horsepower-hour; that is, 2460 ÷ 60.75 = 40.5 pounds.

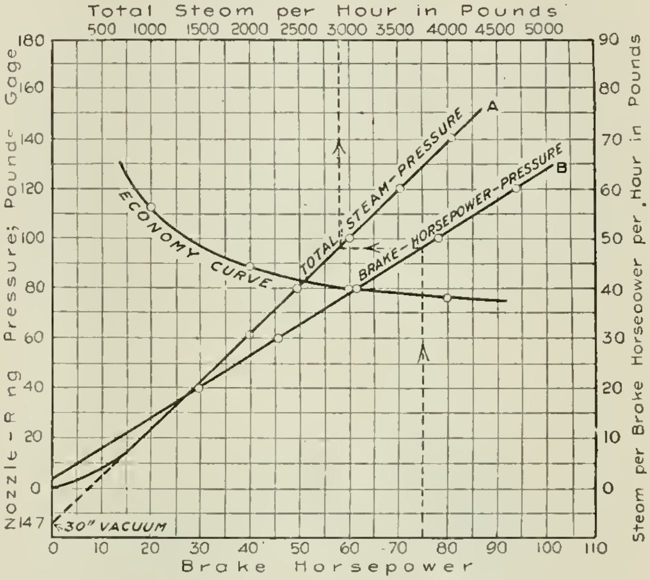

FIG. 5. COMBINATION OF CURVES FIGS 1, 2 AND 3

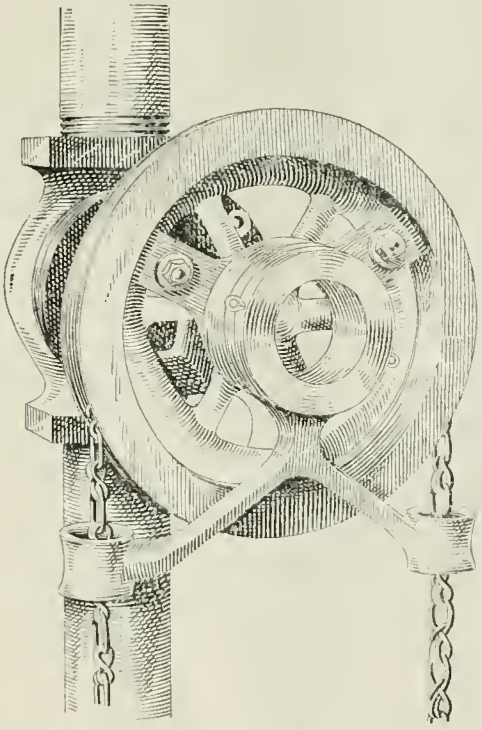
These curves are shown combined in standard form in Fig. 5 together with an indication of the way one point was determined on the economy curve. The steam per brake-horsepower-hour at 75-hp. load is determined by finding 75 on the brake-horsepower line at the bottom of the figure and following vertically to the brake-horsepower-pressure line, then horizontally to the total-steam-pressure line and up vertically to the total-steam-per-hour line at the top of the figure, and read 2900 lb. total steam per hour. The steam per brake-horsepower-hour equals 2900 ÷ 75 = 38.7 lb. Find 38.7 on the pounds of steam per brake-horsepower-hour line on the right of the figure, and run horizontally to the left until the vertical line running from 75 brake-horsepower is intersected, which will give this point on the economy curve.

A power-speed curve, Fig. 4, is plotted to show the variation of power with speed at a constant pressure. This curve is made from tests and is used principally to show the point of maximum efficiency. Sometimes many such curves are drawn at varying pressures and thus indicate the range of the given turbine. As the pressure increases, the velocity of the steam issuing from the jets or nozzles increases, so also the point of maximum efficiency would be at a higher speed, exhaust conditions remaining constant. Windage and friction losses, including also steam friction on the buckets, increase with increased steam and wheel velocity, hence with a given design a limiting pressure will be reached where further increase does not make the point of maximum efficiency lie at a higher speed. It is, of course, desirable to make the pressure and velocity conditions such that this maximum efficiency comes at the point of operation. The operating point is not always the full-load point for this reason:

In many cases the turbine will operate at less day, hence it is desired to have this the best economy condition. Full load would be for such a small percentage of the time that some allowance could be made in the matter of economy.

Improved Rim for Chain-Operated Valve

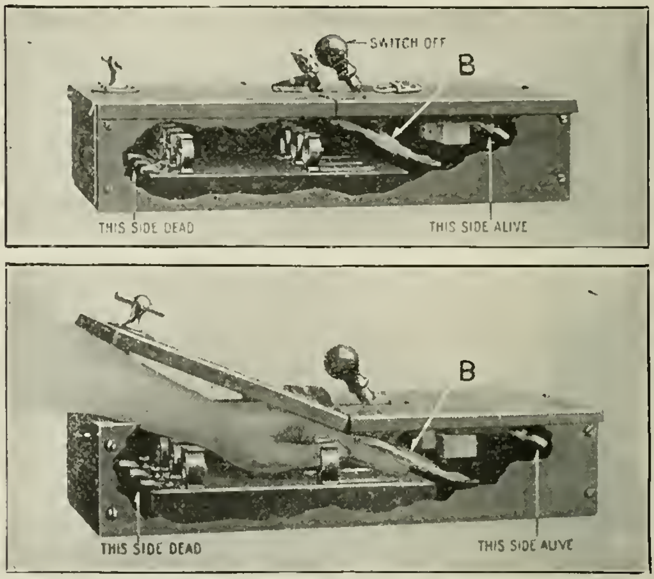
A recent improvement on the Babbitt rim for chain-operated valves, a description of which was published on page 560 of the Jan. 11, 1916, issue of *Power*, is illustrated herewith. By means of this rim, valves may be adapted for operation by chain, the sprocket rim being adjustable to fit different sizes of valve wheels. The improvement consists of a guard having two arms through which the chain passes. In any ordinary installation a guard, to prevent the chain from jumping off the wheel, is unnecessary, but on shipboard or where the valve stem is not horizontal or where other unusual conditions exist, such a device is sometimes advisable. These rims are made by the Babbitt Steam Specialty Co., New Bedford, Mass.



CHAIN GUIDE FOR VALVE WHEEL

Krantz Auto-Lock Switch

Wherever the workmen have little knowledge of electricity, it is desirable to use switches having no live parts exposed or accessible in the ordinary operation of the switches or when replacing fuses. To accomplish this the Krantz auto-lock switch, illustrated, marketed by the Westinghouse Electric and Manufacturing Co., East Pittsburgh, Penn., has been developed and is intended for use on main circuits or wherever an ordinary knife switch is applied. The switching parts and fuses are inclosed in a steel box the cover of which is in two parts, one being screwed on to form a permanent covering for that end of the box containing the switch, and the other part being hinged so as to swing back and permit the renewal of fuses, as shown in the figures. A latching mechanism makes it impossible to open the cover without first throwing the switch to the "off" position and rendering all fuses and other accessible parts dead. As long as the door of the case is open, the switch contacts cannot be closed.



SECTION THROUGH AUTO-LOCK SWITCH. TOP—SWITCH OPEN; COVER CLOSED. BOTTOM—SHOWS THAT LIVE PARTS CANNOT BE REACHED WHEN COVER IS OPEN

Two padlocks can be used independently of each other, so that the switch cover can be locked shut with the switch either "on" or "off," or the switch can be locked in the "off" position with the cover either locked or open. Contact is made by means of a laminated spring-copper brush *B*, double-ended, with auxiliary arcing contacts at each end.

The double-ended brushes provide a double break, dividing the arc between the two ends, each of which is provided with a separate arcing tip. In the closed position the switch is held in positive contact by throwing a toggle over center. A spring provides a quick-break for opening, the mechanism being independent of the operating handle. These switches are supplied for 250, 500 and 600 volts, for either alternating- or direct-current service, and in capacities up to 2000 amperes.

The apparent consumption of crude oil in April was 4.3 per cent. greater than in March, 1918, and 19.9 per cent. greater than in April, 1917.

The Engine as a Reducing Valve

We often see the statement that an engine taking steam at high pressure and exhausting into a low-pressure heating system simply acts as a reducing valve. While this is true in one sense, it is well to keep in mind the difference between the two in the effect on the quality or quantity of the steam. In order to do any work the engine must abstract some heat from the steam. This may demonstrate itself in the form of water in the exhaust steam, being steam that has given up all its latent heat. Under other conditions the exhaust may still be dry saturated steam, but the steam supplied to the engine in this case must have been superheated to a greater or less degree or the steam carried late in the stroke, but there is a loss of heat just the same.

With the reducing valve, however, the case is different; the steam does no work except upon itself. The work done in overcoming the friction or resistance to the passage of the steam through the contracted orifice may be thought of as producing frictional heat that is in turn absorbed by the steam in passing, producing superheated steam at the lower pressure, just as air or water carries away the heat from a brake shoe. There is, of course, no gain in heat in the reducing valve, for it is apparent that it has no means of generating heat; nor is there any loss of heat (except the slight radiation), so there is nowhere else for all of the heat present in the higher-pressure steam to go except to be carried onward by the lower-pressure but slightly superheated steam.

This difference should be kept in mind concerning the use of exhaust steam for heating as against steam from a high-pressure boiler passed through a reducing valve or a contracted orifice such as a partly opened valve. For each horsepower-hour of work done by the engine there has disappeared from the steam not less than 2545 B.t.u. of heat. If an engine takes only 15 lb. of steam to develop one horsepower for an hour, it will be seen that about 170 B.t.u. taken from each pound of steam passing through is enough to account for all the power developed. If the engine takes 30 lb. of steam, half as many (85) B.t.u. will be taken from each pound of steam. To determine the percentage of the total heat taken from the steam in the form of useful work, it is necessary to divide 2545 (the B.t.u. equivalent of one horsepower-hour) by the pounds of steam passing through the engine per hour (the engine's water rate). This gives the B.t.u. taken from each pound of steam; this (with two decimal places added) divided by the total heat in the steam for the given pressure and degree of superheat, if any, as shown by the steam tables, gives the percentage of heat taken from the steam for each horsepower of measured work.

Friction and radiation loss is not taken into account. For example, a water rate of 30 lb. per hp.-hr. gives 2545 ÷ 30 = 85 B.t.u. per lb. taken from the steam, and if saturated steam at 150 lb. gage is used, the total heat of which is 1195, then 85.00 ÷ 1195 = 7.1 per cent. If a separator attached to the exhaust pipe took out all the water, there would be discharged from it about 1¼ lb. of water per horsepower-hour (plus that from radiation), since 30 lb. of steam has given up heat to the extent of the difference between 1195 B.t.u. in steam at 150 lb. gage (substitute any other pressure) and 1150 B.t.u. in steam at atmospheric pressure, or 45 B.t.u. per pound times 30 lb. (or substitute the water rate of the engine) = 1350, a little more than half the total B.t.u. (2545) called for; the remaining 1195 B.t.u. must come from some of the steam giving up its latent heat and returning to a liquid state, to water. In doing so each pound will, of course, give up 970.4 B.t.u., so that 1195 ÷ 970.4 = 1¼ lb. (approximately) of water would result. The radiation loss is no greater than would result from an equal surface and temperature difference, and leakage may or may not be considerable. The 28-odd pounds of dry saturated exhaust steam from this engine is therefore of the same value for heating or like purpose as saturated steam generated at the same pressure in a low-pressure boiler.

U. S. S. "GEM," SCOUT PATROL NO. 41, ASSIGNED TO THE SUBMARINE DEFENSE ASSOCIATION. ONE OF ITS PRESENT USES IS THE TESTING OF VARIOUS SORTS OF FUELS

[It was our privilege recently to take part in a cruise during which the fuel used was powdered coal burned in an apparatus installed by the Fuller Engineering Co. So far as we know this is the first boat to be run with this kind of fuel. The test of "colloidal fuel," which is powdered coal suspended in the colloidal condition in fuel oil, described in our issue of May 28, 1918, wa also made upon the "Gem."—Editor.]

Compulsory Co-operation of Central Station and Isolated Plant

BY S. R. SAGUE

Correspondence with city officials of Cleveland, Ohio, the Fuel Administration and others, concerning the advisability of enforced coöperation of public-service and privately owned plants, so as to avoid duplication of distributing systems and prevent waste of coal.

RECENT experience indicates that, if a statement is repeated often enough, people will come to believe it This seems to be the crux of the central-station controversy with the isolated plant. The central station has declared again and again that it is cheaper to buy power than to make it in individual plants, and it is astonishing to note the inroads that such propaganda has made into good engineering.

In urging the adoption of purchased power the motives of the central station are ulterior. The question as to whether it is better, from a financial viewpoint, for the client to operate his own plant, is never considered Therefore, the writer for several years has endeavored to bring about an arrangement whereby such a matter could be handled as an engineering problem and solved to the best advantage of all. But such coöperation does not exist in the policy of the central station.

Happily, I believe that the day is here when such coöperation must be effected. The large commercial coal requirements of the United States are north of the Mason and Dixon line, and all factories, with but few exceptions, north of this line require heating in the winter. In line with the idea of coöperation, I wrote the mayor of Cleveland, Ohio, on July 10, 1917, the subjoined letter. Cleveland operates a municipal central station erected to compete with the privately owned plant of the Cleveland Electric Illuminating Co., and the rate for service was fixed at one cent minimum and three cents maximum.

I wish to call your attention, at this time, when conservation seems to be the watchword, to a matter whereby considerable saving could be effected in this community in the conservation of coal. A manufacturing city such as ours, situated in a climate subject to the rigors of winter, must have three commodities, inseparably associated; namely, heat, light and power, and all three are derived from coal. To obtain light and power we must produce heat, and to burn coal to produce heat only we lose energy which could be converted to light and power and still leave as much heat for heating as before. To make light and power and dissipate the exhaust steam to the atmosphere or condensers is to lose the heat value of the exhaust steam.

The campaign of the Illuminating company and the municipal light plant to obtain power users is a campaign of inefficiency, at least for the winter months, and one prompted entirely by selfish motives. Both the Illuminating company and the municipal light plant are a necessity, but they do not take a sufficiently wide view of all the requirements of the city for light, heat and power. They emphasize the power and light features to the neglect of the heating, and consequently there is partial duplication of the coal requirements of the city as a whole. The large central stations can make current for power and light cheaper than the small isolated plant; but in the wintertime it is not possible in a majority of cases for them to furnish light and power and have the manufacturer furnish heat, and have the combined cost of light, heat and power as low as though the manufacturer fired his own boilers and obtained light and power to the extent of his requirements, and had his heat besides.

In some cases the coal requirement for heating certain factories is in excess of the requirements of those factories for power, in which case the excess current generated would be disposed of advantageously; for if all boiler plants for heating purposes would, in the winter at least, pass their steam through engines to the extent of the heating requirement, the generators these engines would drive could be paralleled with the distributing system so as to pump back on the line any excess power over the particular factory's requirements, which would then be available somewhere else, where less heat but more power would be required.

The central stations would act to smooth out the system, just as the reservoirs on our water systems take the come and go of daily varying requirements. In the summer all coal would be burned most advantageously at the central stations. This, as regards factory requirements, would taper off in the spring and fall to a minimum in the winter. In the summer, most chimneys, except where process steam is required, would be smokeless, aiding the housekeeper and keeping our city clean when we want cleanliness most. We would not mind our usual soot in the wintertime. By this, 25 per cent. less coal would be burned and real efficiency obtained.

Furthermore, the two power companies are duplicating transmission and going into the same territory. One line or distributing system could be made to do if the municipal light plant and the Illuminating company were hooked in parallel and both delivered power to the same distributing system, just as railroads operate over each other's tracks on an agreed compensation per car mileage, or as oil wells pump into a common pipe line. The oil the pipe line delivers to the owner at the terminal is not the actual oil he pumped, but is oil of the same gravity and test, just as the electricity would be of the same cycle and voltage. There is no more need for two electric distributing systems than there would be for two water systems or two gas systems.

For the city to buy a coal mine and bring in power and light over high-tension transmission lines would not relieve the coal shortage except as regards the use of coal by the light plant, because the same amount of coal for heating must be spent as heretofore, and there lies the great bulk of the manufacturer's real coal problem. This, however, would also help the Illuminating company in case of shortage, if both systems were tied together.

This communication was acknowledged by the mayor, who referred it to the commissioner of light and heat. I next received a letter from the commissioner of light and heat, which, for various reasons, I prefer to withhold in this communication, but its context may be surmised from my reply of July 27, 1917, as follows:

I am afraid you overlooked the main point in my letter, namely, heat as well as light and power; also, it was my intention to treat of power users or factory loads entirely, and not domestic.

It is manifestly impossible to heat either a factory or a home with electric current, no matter how cheaply you get your coal. One unit of electricity costing one cent is equivalent to 3413 B.t.u. One pound of coal contains, say, 13,000 B.t.u., and one ton would then contain 26,000,000 B.t.u., and using arbitrarily an efficiency of 50 per cent., which is low, you would get 13,000,000 B.t.u. from a ton of coal, which would be equivalent to 3809 units of electricity costing $38.09 on a basis of one cent per unit. With coal at even $10 a ton the domestic user could not afford to heat electrically, much less a factory using even cheaper steam coal.

Any proposition covering the generating of current either here or at a mine must be on the basis of power and light only—not heating. You will see that the point of my letter dwelt largely on the question of heat in combination with light and power. They cannot be separated, as all originate from coal, and any factory requiring heat makes a potential light and power equivalent whether it knows it or not. In other words, if each pound of coal could be made to deliver its total equivalent in heat as well as in light and power, we would make enormous savings.

You lose sight entirely of my suggestion of one distributing system for both plants. This would immensely improve the load factor, which you say is desirable. The stand-by losses and reserve apparatus necessary for sudden increases in load would be reduced by one common distributing system, as these items are now in duplicate, whereas only one set need be held for emergencies. In fact, by an equitable arrangement with the Illuminating company, the municipal light plant could be run at a maximum at all times, whether generating here or at a mine, pumping its current into a common distributing system.

You state that the immense heating load comes on in winter, requiring enormous capacity. This is not so if you arrange one distributing system and have each factory make current, using exhaust steam therefrom to an amount necessary to heat, and pumping any excess current generated back on the line for use elsewhere. I still feel you have missed the point of my letter and the thought contained therein, and your solution still must consider heat, light and power inseparably in the commercial field at least, which in turn will aid the domestic field on light and power only. Electric heating is a mirage.

To this I received no reply—central stations do not like to discuss heating—but it illustrates how any effort is smothered. Along this line, I sent a circular letter to a list of power users. One of these letters was forwarded to some central station, with the result that I received a letter from the Society for Electrical Development, Inc., as follows:

Our attention has been called to a circular letter sent out over your name, advocating the installation of isolated industrial plants, and claiming that it is more economical to burn coal in such isolated plants than it is to take central-station service, the claim being made that this is one way of conserving coal. The letter speaks of statistics proving this. We are very much interested in the subject and would appreciate it if you would kindly send us the figures upon which this statement is based.

To this I replied under date of Mar. 13, 1918, as follows:

The writer was interested to receive your communication. We are rather under the impression that your society is, as the letterhead states, a corporation for coöperation, but only so far as it benefits the central station. We may be misinformed in connection with this and, if so, would appreciate your setting us straight.

We, in our work, have endeavored to view the positions of the central station and the isolated plant from an engineering standpoint, and make no effort to encourage the installation of an isolated plant where we believe central-station service is the best. However, we believe that the central stations do not take this attitude, but claim that the installation of central-station service is always best, speaking from the user's standpoint. With this position we cannot agree.

We cannot conceive that central-station service is more economical where the heating load is the principal item to be considered. The central station has made an effort to shut down many power plants where the coal consumption for heating has been equal to or greater than the actual amount of coal required for power purposes. During the winter months, this requires the plant so served to burn the same amount of coal as previous to its connection to the central station, and also compels the central station to burn additional coal for supplying the power formerly supplied in the isolated plant, which still retained exhaust steam for heating.

You are entering into a discussion which has a great many ramifications, and the answer to the argument is the particular installation under discussion at the time. A general blanket answer cannot be formed.

The average manufacturer is less posted on his power plant than on any other department of his establishment and is subject to the influence of a salesman who can often put before him figures which are not borne out by facts. We are sorry to say that many installations in this territory have been made for central-station connections on this basis, rather than on the basis of engineering. It is also a question as to where the central station becomes large enough to have economies such as will enable it to sell advantageously to a user whose isolated plant is of such size that reasonable economies could be secured in it.

We believe that the Society for Electrical Development, Inc., should establish a policy and recommend to its associates the inadvisability of having solicitations made for the purpose of getting central-station connection regardless of the actual figures entering into the engineering requirements. You must admit that power generated from the coal required for heating during the winter months is a byproduct of considerable value, particularly in the face of the present price of coal, and this value is a national asset which should be conserved, even if it does not tend to the direct interests of the central stations to conserve it.

We have had the pleasure of recommending central-station service in a great many instances, and probably have as much apparatus connected on the central-station service as any company in the United States, from our motor sales department; but we must consistently recommend either central-station connection or the installation of an isolated plant on the basis of the best interests of the person served.

In response I received a very courteous letter of acknowledgment, to which I replied as follows:

Most certainly we believe in central stations. They are as necessary to our economic development as water-works or street cars; but we do take issue with central stations when they endeavor to secure connections which, upon careful investigation, show not to be to the advantage of the subscribers. When we speak of central stations, we mean such large installations operating condensing, as can show economies superior to the average isolated plant, when the cost of generating current alone is considered; but we do not believe that the average central stations, so called, in some of the smaller towns, are in position to compete with isolated plants of sometimes approximately equal capacity, particularly when the reclaimed value of the exhaust steam is available for heating. With the small central station, running noncondensing, such heat is thrown into the atmosphere or, if running condensing, into the condensers. This heat is a manifest loss and should be, as far as possible, conserved with the idea of cutting down the coal requirements of the country to the lowest possible point.

However, this was referred to the Fuel Administrator, and I was in due time written by him, whereupon I replied as follows:

To answer your question, let me ask you another: If a firm requires 100 boiler horsepower to heat a factory (say 3300 lb. of steam per hour at 5 lb. pressure) and is buying from the central station 1000 kw.-hr. per 10-hour day to operate machinery, what is the national coal loss in that individual case per day?

Answer: The amount of coal used by the central station to generate the 1000 kw.-hr.

You will agree that the following statements are pertinent to the discussion for the northern section of this country, which is the large coal-using as well as manufacturing section of the nation:

1. In this latitude for five months we positively must heat our factories.
2. Fuel transportation during the heating season is more difficult than during the nonheating period.
3. Complete recovery of all values (heat, light and power) from every pound of coal is necessary, particularly during the heating season.
4. The isolated plant during the nonheating months may lose some of the gain made during the heating months.
5. Eliminate, as much as possible, during heating months the enormous heat values dumped into condensers by central stations to make low generating costs.
6. Burn coal economically in isolated plants to heat by exhaust steam and use current generated as well for power.
7. Admit the economic necessity of central stations and isolated plants.
8. Connect to the central station where economies can be shown to be in its favor.
9. Operate isolated plants where coal savings warrant.
10. Review the entire matter from an engineering standpoint.
11. Prevent solicitation of commercial enterprises as power users by central stations for selfish gain, regardless of the national coal pile.
12. Prohibit central stations from taking on power users at a lower rate than cost to produce current for the purpose of keeping up volume in central station.
13. Compel isolated plants to arrange to burn coal eco-

nomically. Allot isolated plants only such coal as they would require if operated economically, thereby compelling savings by the installation of economical apparatus.

No acknowledgment was received, so I wrote again:

> We had the privilege of writing you with reference to isolated plants versus central stations as power-producing units, and their advantages from the coal-saving standpoint. Up to the present, the writer has not had the pleasure of hearing from you further, and wonders if he can be of any assistance to you in this matter.
>
> We recognize that it is not advantageous for the central station to name a rate for short-time connection, such as the summer months; but if the central station were paid an amount for the nonheating season for power on the basis of the cost of producing the power in each individual isolated plant, it would be decidedly to the advantage of the central station to accept such a connection, and it would not be to the disadvantage of the proprietor of the isolated plant to pay to the central station the amount which he otherwise would have paid anyhow.
>
> In this way we would throw the load on the central station, with a minimum of coal consumed in the summertime, and throw the load on the isolated plants and conserve the heating value of the exhaust steam in the wintertime, and make a tremendous saving all around.

So far, no acknowledgment has been received.

Now, the whole system is one of inherited policy—a selfish policy, a policy of "get while the getting's good"; but a foolish policy, a policy founded upon apparatus in isolated plants of a design and pressure of thirty years ago, a policy which the central station thinks is advantageous to them when, in fact, it is not, if they would view it from the standpoint of good engineering.

The central station should get some load from all. If such a policy had been in effect prior to the war, how flexible would have been our response! We could quickly arise to the requirements, instead of having thousands of important industries hanging upon the hope that nothing will happen to the central station. A flash on some turbine would shut down thousands, while trouble with an isolated plant is more quickly repaired and affects only those workmen in the one plant.

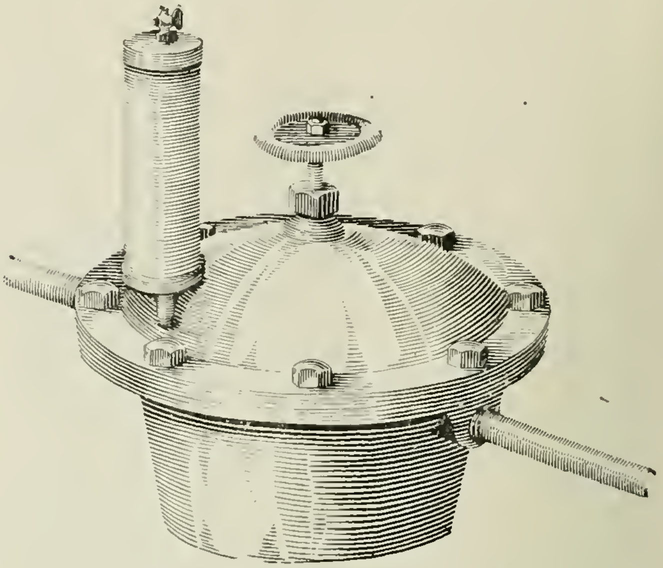
Saving coal is possible only to the extent that we can recover all values of heat, light and power, and charters for public utilities should require a filed report of all conditions of each prospective central-station user, from an engineering standpoint. This report would be referred to a properly constituted committee of disinterested engineers who would issue a permit for a given number of units from the central station per year, which would be the total amount required less the number of units that could be generated by the coal used to heat by apparatus of maximum economy.

[Through the influence and the financial assistance of the National Council of Defense, an agreement has been entered into between the Cleveland municipal light plant and the Cleveland Electric Illuminating Co., providing for an exchange of power between the two. The electrical connection of the two stations will practically guarantee war plants against shutdowns due to failure of power.—Editor.]

Air-Bound Steam Traps

By M. A. Saller

In a woodworking plant a number of live-steam coils were used for drying lumber, and these coils were drained by high-pressure steam traps. Because of the air which found its way into the coils, the traps became airbound and sluggish in operation. Instructions were given to open the pet-cocks and blow out the air from the traps at frequent intervals, but as is often the case, the instructions were soon overlooked. The engineer equipped each of the traps, as shown in the illustration, with an extra chamber made of pipe fittings, giving added space for the air so that the traps would operate a longer period without attention. Such an auxiliary chamber might be used to advantage in other cases where similar trouble occurs.



AIR CHAMBER ATTACHED TO STEAM TRAP

Method of Squaring Mixed Numbers and Extracting Square Roots

By John S. Carpenter

No claim of originality is made for the following method of squaring or extracting the square root of mixed numbers, as it is an application of the binomial theorem, but in fifteen years of practice I have never seen it introduced by anyone else. It is used with accuracy on the slide rule when there are decimals to be obtained. To the average operating engineer the conventional method has its terrors. This way involves very simple operations which are easily checked, at a glance in many cases. Most tables do not have squares of fractions.

Let it be required to square such an awkward number as $14\frac{1}{4}$. From a table or the slide rule we have as the square of 14 the answer 196. Now to this add twice fourteen times $\frac{1}{4}$, which is 7; also add the square of $\frac{1}{4}$, which is $\frac{1}{16}$; the total is then $203\frac{1}{16}$. Try another, say $30\frac{1}{8}$. The square of 30 is 900; twice 30 times $\frac{1}{8}$ is 7.5; $\frac{1}{8}$ squared is $\frac{1}{64}$, or 0.015625; adding, we have 907.515625 exactly.

Let it be required to extract the square root of 1121.56. Looking down the column of squares in a table, we see that the square of 33 is 1089; deducting this from 1121.56 leaves 32.56; dividing this by twice 33 gives 0.493; the answer then is 33.493. If we quibble over the last figure, square 0.493 and deduct it from 32.56, which is then 32.32; divide anew by twice 33, and we have 33.490, a little closer. For most purposes it will not be necessary to deduct the second square.

In a drafting room where the grade of help was not of the best, men who fell down repeatedly on the conventional method mastered this one with ease.

About Preventable Boiler-Room Losses

The shadow of the central station looms over the head of an engineer of an isolated plant. He is told of a few things that could be done to better the condition of his boilers and is promised a surprise in the difference in fuel consumption if the suggestions are carried out.

ONE evening as Willis was making his way home from his plant he went by a roundabout way and stopped in to visit with Joe Beards, the engineer at the Bartlett Tool Works. The plant consisted chiefly of four return-tubular boilers, and a Corliss engine drove a generator that supplied power and light for the plant.

"How goes things?" asked Willis, as he helped himself to a chair and lit his favorite pipe. "You got through the coal shortage without getting down and out, I hope."

"Just about and no more," answered Joe, seating himself in another chair. "Some days I was on the ragged edge of nothing, as you might say, and the boss was about to throw up his hands, shut down the plant and run with central-station service. He says they have given him figures that about convince him it would be cheaper in the long run. If he does that, it will let me out, that's sure, but I don't see that I can do anything about it, do you?"

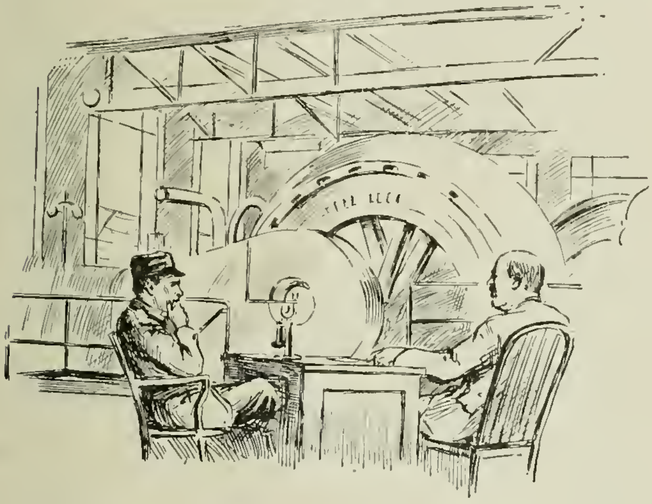


FIG. 1. "I NEVER RAN A BOILER TEST AND NEVER EXPECT TO," SAID JOE

"Joe, if it were my plant, I believe that I would have considerable to do about it. If it were my plant, I would take figures to the 'old man' and show him that he could run his own plant cheaper than he could buy outside current."

"You might do it with your plant, but I can't with mine because I don't know what the operating costs are."

"Well," replied Willis, "if I were you I would get busy and get some inkling as to what it was costing to run this place. You certainly can stop all preventable waste whether you know what it is costing each year to operate or not. Take, for instance, your boiler room. How great are the preventable losses? You say you don't know, but I take it that your plant is no better than the average, and if that is so about 8 per cent. of your furnace losses in fuel consumption could be cut out. Because you burn a lot of coal is no reason to assume that you are making a lot of steam. Some furnaces can make a boiler evaporate an average of, say, 9 lb. of water per pound of coal, and the best that is obtained from others is about 6 lb. of water per pound of coal. Now with which do you think your outfit averages up?"

"I don't know," answered Joe. "I never ran a boiler test and never expect to; in fact, I don't know how. What good would it do, anyway?"

"Well, seeing that you have mentioned it, a boiler test wouldn't amount to much unless your boilers and furnaces were in fit condition in the first place. There wouldn't be much use in starting anything of that sort, because a satisfactory test cannot be had unless the furnace is in shape, and furthermore, when it comes to evaporation tests, the kind of boiler that is put over a furnace cuts a big figure, and more than that, the condition of the boiler cuts still another figure."

"Hold on a minute before you get all out of breath," interrupted Joe. "You just said that some tests will show an evaporation of 9 and some 6 lb. of water with each pound of coal burned. What's the reason?"

"Generally, it is because one furnace is better than another, although the quality of the coal will have a lot to do with it, as well as the condition of the boilers. A furnace, to be efficient, must be one that will burn the most combustible with the least surplus of air."

"How are you going to find out what is the proper amount of air?" was Joe's next question. "You can't see how much air is going into the furnace."

"By gum, that's right, I hadn't thought about that; but for all that you can tell all right if you only know how, and that is by a flue-gas analysis. When you burn a fuel in a boiler furnace, you will get two principal gases, carbon dioxide (CO_2) and carbon monoxide (CO), and the amount of each in the flue gases is determined by the amount of air that gets into the boiler furnace. The greater the volume of excess air the lower the percentage of CO_2 and the greater will be the loss in fuel. Reasonably good practice will call for about 40 per cent. excess air, which would give about 14.5 per cent. CO_2. If the excess air is raised to, say, 100 per cent., the percentage of CO_2 will decrease to about 10, and the fuel loss will be about 17 per cent., and the more excess air that gets into the furnace the lower the CO_2 and the greater the fuel loss."

"A fellow was telling me something about CO_2 awhile ago," remarked Joe. "He said that a smoking chimney meant low CO_2. If that is the case, I guess Joe Simmons over at Skinner's factory must be having a steady run of low CO_2, because his chimney smokes about all the time."

"I calculate you ain't making any mistake in your assumption, but don't you kid yourself into believing that it's the smoking chimney only that indicates poor furnace conditions. A clean chimney may show, and at the same time four or five times the proper amount of air may be passing through the furnace and over the boiler-heating furnace with the corresponding low CO_2."

"As far as I can see," said Joe, "you have to have an instrument to find out what the CO_2 is in the flue gases, and it costs money. In this plant I don't see that I will get very far as an expert operator of a CO_2 machine."

"Perhaps not just at present; but if you'll do your part, I don't think you'll have any difficulty in getting any apparatus to assist you in running the plant cheaper. One thing you can do for a starter is to either buy a draft gage or make one. They don't cost much, but if the company can't raise the price, you can make one by bending a piece of glass tube into the form of U-tube" (Fig. 2) "and connect one end of the tube to the furnace. The draft in the furnace is of more importance than most engineers seem to think, and it has a good deal to do with the amount of coal you burn. Then you should also have a thermometer for taking the temperature of the gases going to the chimney. The furnace temperature of a boiler will be around 2400 deg. The more heat that is absorbed by the boiler heating surface the lower the temperature of the gases going to the chimney. Now, what do you get?"

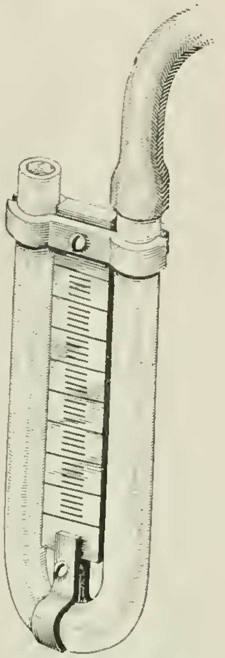

FIG. 2. HOME-MADE DRAFT GAGE

"Search me, I never had a thermometer in the place. About what should I be getting?"

"I take it that you are getting close to 600 deg.; probably higher. You likely have scale on the shell and tubes of your boilers, soot on the inside of the tubes and cracks in the brick setting. Outside of that and a leaky safety valve and a blowoff valve, I guess your boilers are about on the average."

"How do you know that there is scale in my boilers, soot in the tubes, leaky valves and cracks in the boiler setting?" asked Joe in surprise.

"Deduction, Joe, nothing else. I know the rest of us engineers in town have scale and enough of it to fight, and it keeps us on the jump, so to speak; but in the last six months you haven't cleaned your boilers—you told me so—therefore they must have scale. As to soot, you haven't anything but a piece of pipe to blow tubes with and it is covered with cobwebs. I saw them when I came through the boiler room, as I also saw the cracks in the boiler setting. The cobwebs show that the blower had not been used for some time, and the cracks show no signs of any attempt having been made at stopping them up. The escape pipes of the safety valves were dripping water and leaking steam, and the blowoff pipes were hot when I passed them; both sure indications that they leak, and that is about enough for one time.

"The thing for you to do before you begin to bother with CO_2 is to stop up the cracks in the boiler settings, clean out the scale in the boilers, blow the tubes every day and scrape them at least once a week. Don't forget to grind in the safety valves as well as the blowoff valves. I know your safety valves are of the old ball-and-lever type and should not be allowed to be used, but they'll have to go for awhile, I take it. I'll bet you a bag of peanuts that you'll see a difference in the coal bill if you will fix things up as they should be. If your chimney-gas temperatures are high now, and I guess they are, you will find that with clean boilers they will be lower; yes, considerably lower.

"Then you will find that your fireman won't have to force the fires so hard. You see, it is only necessary to keep the temperature of the combustible gases high enough to allow of their combustion. An extremely high temperature, while it has advantages, also has disadvantages due to the danger done to the furnace lining. High temperature in the rear of the combustion chamber is not an evidence of efficiency, as it may be caused by the gases being burned in the rear connection, and striking the cooler heating surfaces of the boiler, these gases will pass to the chimney but partly consumed. The hotter the gases entering and leaving the tubes the more heat is wasted in the chimney.

"Then for a change you might go into the boiler room a little more frequently and jack up the firemen once in a while just to let them know who is boss. I noticed as I came past the ash pile that there were some mighty big clinkers."

"Yes, I have noticed that myself. It must be the coal we have been getting."

"Perhaps it is," answered Willis, "but I'll make a guess that it's because the firemen carries thick fires and keeps stirring them up. That will do it, and running with the ashpit doors closed, which preheats the air in the ashpit before it goes up through the grate, will help make them."

"I don't see what a thick fire has to do with making clinkers," said Joe, as he glanced at the clock to see how near shutting-down time it was. "We have to carry enough fire to take care of the load, that's certain."

"I'll tell you what it does. A thick fire cuts down the air supply and so lets the ashes become heated. If plenty of air passes through the fuel beds the air absorbs the heat in the grate and ashes and keeps them comparatively cool. When the fireman runs a bar under his fire to break it up, he brings ashes up into the fuel bed where it fuses and forms clinkers. This lifting of the ashes and clinkers from the grate allows the live coal to fall upon them and this will overheat the grate. The thicker the ash bed and clinker the greater is the air supply cut down. It is better to carry a thin fire because a better air supply is possible if you do."

"All right, Willis, you have had quite a whack at lecturing on do and don'tless things. You told me to get a draft gage. Now, tell me, what shall I do with it after I get it? What work will it do in the first place or any other place?"

"Well, you lunkhead, a draft gage will tell you how much draft measured in inches of water you are getting. For two cents you can't tell whether the draft is poor or good, as the case might be. A draft gage will tell you what draft you are carrying, and it is of considerable importance. If there wasn't draft, there wouldn't be much of a fire in the furnace. If there is too much draft, there is the danger of getting too much air, which would reduce the CO_2 we have been talking about.

"To burn coal to the best advantage, the draft must be regulated. You cannot regulate your draft unless you know what it is, and if you will try it out you will be surprised at the difference such a small item as a twentieth of an inch in a draft will make in the amount of coal burned.

"With the boiler run at its rating, the approximate draft will be about 0.25 in. of water, but you would have to experiment to find out what would be the best draft to carry with your load and boilers. The least draft that you can carry and still make steam for the load to be carried, the better, although this can be carried to extremes in cases where the grate area is excessive. The only proper way to know the correct draft is to analyze the flue gases, which you can't do as yet. The damper is the proper method of regulating the draft, although many firemen will do so largely by closing the ashpit door, and in doing this the air pressure is increased on every other part of the boiler settings where cold air reaches them, and the more cracks in the boiler settings the more air is drawn into the furnace through them.

"You take my advice and get after a few of the things around the plant that are helping to prevent Uncle Sam from licking Kaiser Bill and at the same time are working you out of a job, and see if things don't look a little brighter as far as keeping your plant going is concerned if no more. Now don't throw up your hands and say it can't be done. Think it over, and while you are doing that I'll toddle along home and shake my fist at the table."

Purchasing Power-Plant Equipment

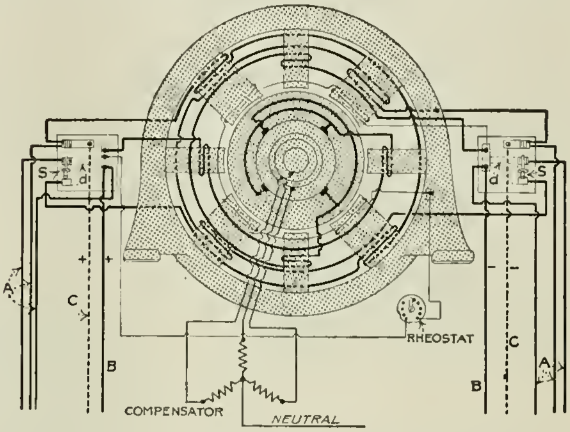
Cases are all too common where the purchaser is seemingly unaware of the operating characteristics of the machinery being bought, when considered in relation to its operation with machinery previously installed, and where the builder's representative gives the desirable features only of the new equipment and says nothing about the changes in the existing plant that he knows will be absolutely necessary to the operation of the plant as a whole after the proposed machinery is installed. One instance in mind will emphasize the need of a more candid exchange of engineering knowledge between the manufacturer's representative and the purchaser, especially when it is evident that the latter is not technically up on the problem under consideration.

Previous to my connection with my present employer, the management bought a motor-generator set, which was installed in one of the plants being gradually changed over from direct to alternating current. The plant at that time contained three direct-connected 220-volt direct-current units, all of which were compound wound. These units were operated on a 110- to 220-volt three-wire system, with the neutral taken from a motor-generator balancer set.

The new motor generator consisted of a 2300-volt three-phase 60-cycle synchronous motor driving a 220-volt interpole compound-wound three-wire direct-current generator, with collector rings outside of the commutators to which the star-connected compensator for the neutral was connected.

The purchaser undoubtedly did not know and the builder did not mention the probable trouble ahead until the machine was installed and attempts were made to parallel it with the 220-volt compound units and balancer set. The result was so disastrous that the erector cut out the split series-field winding, making the machine a shunt interpole three-wire generator, with the result that it could not be made to carry its rated load even when all the shunt-field resistance was cut out and the brushes shifted to a point where destructive sparking occurred.

An expert, sent out by the manufacturing company to investigate the trouble, spent several days testing the machine and reported that it worked perfectly as a compound generator, and for the first time called the purchaser's attention to the fact that the other compound-wound machines to operate in parallel with the new one should have their series-field winding split and additional cables, switches and circuit-breakers would be necessary and additional busses would have to be installed. This meant considerable expense at a time when an effort was being made to change over to alternating current, and the matter was dropped with hard feelings all around, the machine being operated as a shunt machine under partial load until such time as enough of the direct-current load was connected to the alternating-current system for the motor-generator set to take care of the direct-current service. Then the series-field winding was connected back into circuit with a switch mounted in each terminal block, as shown at *S* in the figure, so that the series-field winding could be short-circuited whenever it was necessary to operate this machine with other direct-current units.



CONNECTIONS OF THREE-WIRE GENERATOR

With the switches closed the machine operates as a direct-current shunt generator, and with the switches open the armature current passes through the compound winding, giving good voltage regulation and making the machine available for a full load.

The six heavy lines *A* and *A* in the figure show the main leads as it was intended to connect up the machine. *B* and *B* are positive and negative leads as run by the manufacturer's engineers, thus leaving the series-field winding cut out of circuit. The dotted lines *C* and *C* show positive and negative leads as now run to the switchboard, and the dotted section *d* and *d* shows the connection between the series-field and the interpole windings.

The Electrical Study Course—Losses in Direct-Current Machinery

The losses in direct-current machines are friction, excitation, armature-copper losses and core losses. These losses are discussed, and the method of determining the efficiency of a generator is given.

WHENEVER energy is changed from one form to another, there is always a loss in the transformation. For example, the amount of energy transmitted by the steam to the cylinder of an engine in the form of heat is not all available at the flywheel to do useful work. A large percentage of the energy actually supplied to the engine is lost in the exhaust, in radiation from the surface of the cylinder and in overcoming the friction of the moving parts, etc.

What has taken place in the engine is, the energy in the steam has been converted into a mechanical form of energy which may be used to do the mechanical work of driving any kind of machinery. If the engine is used to drive an electric generator, then we will have another transformation of energy; that is, the mechanical energy transmitted to the engine's shaft or flywheel will be converted into electrical energy and transmitted through the circuits to the devices supplied by the generator. In this transformation from a mechanical to electrical energy there is also a loss just as in the steam engine; that is, if the energy delivered to the engine's flywheel is capable of developing 100 hp., then less than 100 hp. will be delivered to the circuits. Part of the power developed at the engine shaft will be expended in overcoming the friction of the moving parts of the generator, exciting the field coils, the losses due to the resistance of the armature circuits and eddy-current and hysteresis losses.

FIG 2

FIG. 3

FIG. 4

FIG. 5

FIGS. 1 TO 5. ILLUSTRATE HOW IRON MOLECULES ARE SUPPOSED TO ARRANGE THEMSELVES WHEN UNDER THE INFLUENCE OF A MAGNETIC FIELD

The friction losses in a direct-current machine consist of the friction of the bearings, brushes on the commutator and the friction of the air upon the revolving element. The last item is usually known as the windage losses. The total friction losses amount to about 6 per cent. of the capacity of the machine for a 1-kw. unit to about 3 per cent. for a 1000-kw. unit. These may be considered as the mechanical losses of the machine; that is, they represent mechanical power that has been supplied to the generator and that has not been converted into electrical power, but has been expended in doing the mechanical work of overcoming the friction of the generator.

The current that is used to excite the field coils represents electrical power that has been generated in the armature, but is used up within the machine to energize the field coils, therefore is not available for doing work outside of the machine. The amount of power required to energize the field coils of direct-current machines is about 6 per cent. of the total output for machines of 1-kw. capacity to about 1.4 per cent. in 1000-kw. sizes.

Since the energy expended in the field rheostat is also charged up against field losses, the power loss in the shunt-field winding is practically constant, being only changed slightly by the hand adjustment of the rheostat. The losses in the shunt-field winding are therefore equal to the volts at the armature terminal times the current supplied to the field coils.

The energy expended in the field coils is sometimes referred to as the excitation losses or I^2R losses in the shunt-field winding; that is, the loss in the field coils is equal to the square of the current times the resistance of the field coils and that of the section of rheostat in series with the coils. For example, the total resistance of a shunt-field circuit is $R = 27.5$ ohms, and the voltage at the armature terminal is $E = 110$; then the current flowing in the field coils is $I = \frac{E}{R} = \frac{100}{27.5} = 4$ amperes, and the watts $W = EI = 110 \times 4 = 440$. The watts are also $W = I^2R = 4^2 \times 27.5 = 4 \times 4 \times 27.5 = 440$, which gives the same result as the former method.

In the previous lesson we found out that a part of the voltage generated in the armature was used up in overcoming the resistance of the armature windings to the flow of the current. This also represents a loss of power supplied by the prime mover to the generator. This loss is usually called the armature copper loss, or I^2R loss, and is one of the chief factors in increasing the temperature of the machine. The power loss in the armature copper is equal to the voltage drop through the armature winding times the current supplied by the armature; it is also equal to the square of the current times the resistance of the armature winding.

For example, the resistance on a given armature is $R = 0.1$ ohm, and the total current supplied to the load and shunt-field winding is $I = 150$ amperes; then the volts drop in the armature is $E_d = IR = 150 \times 0.1 = 15$ volts, and the watts loss in the armature is $W = E_d I = 15 \times 150 = 2250$ watts. The watts loss is also $W = I^2R = 150 \times 150 \times 0.1 = 2250$.

The losses in the armature copper vary from about 4 per cent. of the capacity of the machine in 1-kw. units to 1.8 per cent. for units of 1000-kw. capacity. These losses vary as the square of the current supplied by the armature and are practically zero at no load, being only those due to the shunt-field winding current, and at a maximum value at maximum load. The resistance of the armature circuit is usually considered as that of the armature windings, brushes, series-field windings if the machine is compound-wound, and the machine leads and terminals.

In the lesson on direct-current armature constructions in the Jan. 13, 1918, issue, it was shown that when the armature core is revolved between the polepieces, it cuts the lines of force and therefore generates a voltage the same as the windings do. It was also shown that the current caused to circulate around in the core by this voltage, or eddy current as it is called, created a pull that opposed the turning effort of the prime mover driving the generator, consequently represented a direct loss of power. The eddy-current losses are usually combined with the hysteresis losses and are called the iron or core losses.

The hysteresis losses are those which are due to the friction of the molecules, of the iron in the armature core, on each other as they align themselves with the lines of force when the armature is revolved. This is illustrated in Figs. 3 to 5. In the lesson "Elements of Magnetism—II," in the Jan. 30, 1917, issue, it was explained that a piece of iron acted as if each molecule was a magnet having a north and a south pole, and that under normal conditions the molecules arrange themselves so that the N and S poles of one molecule were neutralized by the N and S poles of other molecules and thus form a neutral condition, as in Fig. 1. When the piece of iron is brought under the pole of a magnet, this pole will attract the opposite pole of the molecules of the iron and cause them to be arranged in a systematic group, as in Fig. 2, thus producing a N pole at one end of the bar and a S pole at the other. In the same way, when the field poles of an electrical machine are magnetized, they cause the molecules in the armature core to arrange themselves systematically as in Fig. 3. Now if the armature core is turned 90 deg. from the position in Fig. 3, as in Fig. 4, it will be seen that although the core as a whole has revolved 90 deg. to the left as indicated by *AB*, the field magnets have held the molecules of the iron core in the same position in each case. For this to be possible the molecules have done what is equivalent to turning to the right 90 deg. If they had remained in a fixed position in the core, the condition that would exist is that in Fig. 5, from which it is seen that if each molecule turns 90 deg. to the right from the position in the figure, a condition exists in the core corresponding to that in Fig. 4. This is just what appears to be going on in the armature core all the time that it is revolving and the field poles are magnetized. As the armature revolves as a whole in one direction the molecules are revolving about their axis in the opposite direction. The molecules revolve at the same rate as the armature core in a two-pole machine, or one revolution for one pair of poles. The latter statement conforms to the condition existing in all multipolar machines; that is, the molecules make a complete revolution about their axis for each pair of poles in the machine. In a four-pole machine they would be revolving twice as fast as the armature, in a six-pole machine three times as fast, etc.

To cause the molecules to revolve about their axis requires a certain amount of power. The power that is expended in changing the position of the molecules is the hysteresis losses in the core. This, combined with the eddy-current losses, is called the core losses, and amounts to about 4 per cent. in machines of 1-kw. capacity to about 1.2 per cent. in 1000-kw. machines. If an attempt is made to turn the armature of an electrical machine by hand, with the field poles dead, it should turn very easily, but when the field poles are magnetized, it will be found that a greater effort must be developed to turn the armature. This increased effort required under the latter condition is due almost entirely to hysteresis, or in other words, to rotating the molecules of the core.

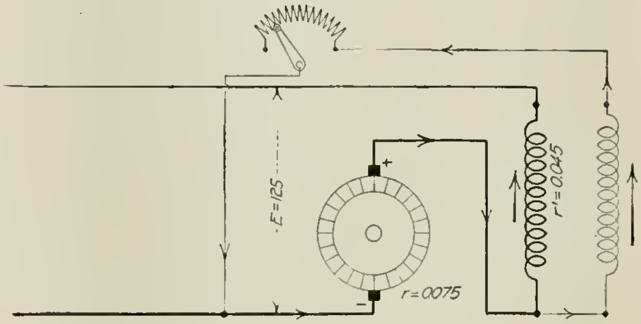

FIG. 6

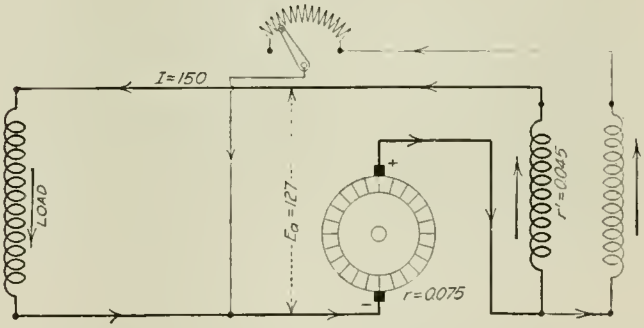

FIG. 7

FIGS. 6 AND 7. DIAGRAMS OF COMPOUND GENERATORS

The total losses at full load in a 1-kw. machine amount to about 20 per cent. of the output, while in the 1000-kw. machine they are about 4.5 to 5 per cent. In other words, when a 1-kw. machine is delivering its full-rated load (1-kw.) it will require about 1.2 kw. to drive it, and when a 1000-kw. machine is delivering its full rated load (1000 kw.) it will require about 1050 kw. to drive it.

The ratio of the output of a given machine to the input is called the efficiency and is usually expressed in a percentage, thus: Per cent. efficiency $= \frac{\text{output} \times 100}{\text{input}}$, from which, output $= \frac{\text{input} \times \text{per cent. efficiency}}{100}$, and input $= \frac{\text{output} \times 100}{\text{per cent. efficiency}}$.

For example, a given generator requires 50 hp. to drive it when supplying 32 kw. to a lighting system. Find the percentage of efficiency that the machine is operating at.

The input in this case is horsepower, kilowatt $= \frac{\text{hp.} \times 746}{1000} = \frac{50 \times 746}{1000} = 37.3$; then per cent. efficiency $= \frac{\text{output} \times 100}{\text{input}} = \frac{32 \times 100}{37.3} = 86$ per cent. approximately. That is, only 86 per cent. of the power supplied to the machine is available for doing useful work in the lighting system.

The problem given in the last lesson is shown in Figs. 6 and 7. The resistance of the armature and series-field winding is $R = r + r' = 0.075 + 0.045 = 0.12$ ohm. At no load the machine develops 125 volts. When the armature is supplying a current $I = 150$ amperes to an external circuit, as in Fig. 7, the volts drop through the armature and series-field winding is $E_d = RI = 0.12 \times 150 = 18$ volts. The load current flowing through the series-field winding was assumed to have caused the armature to generate 20 volts more than at no load, or a total $E = 125 + 20 = 145$ volts. The load current caused 18 volts drop, then the volts across the line terminals is $Ea = 145 - 18 = 127$, or an increase of $127 - 125 = 2$ volts.

A given shunt generator when supplying a constant load requires 175 hp. to drive it, and the voltage at the armature terminal under this condition is 115. The core losses of this machine amount to 4.5 hp., the field winding resistance is 11.5 ohms, the armature copper losses are 3500 watts, and to overcome the friction on the machine requires 1.5 hp. Find the percentage of efficiency at which the machine is operating.

Commutator Was Strained

By E. C. Parham

The general practice in tightening commutators is to heat them first so as to soften the insulation and thereby make it more yielding to the pressure; the resistance then offered to the tightening of the nuts gives an indication of how tight the construction is. One method of heating large commutators, after the machine has been installed, is to apply a number of gasoline torches around the periphery while the armature is kept rotating fast enough to prevent overheating in spots. Another method is to operate the machine with load and with the brushes shifted to a position that causes considerable sparking.

A large generator gave trouble by sparking at the brushes, which was attributed to loose commutator bars. According to the operator's statement, the commutator when the machine was installed was a little out of round, as indicated by the brushes riding up and down once per revolution. Slight eccentricity of the commutators of an engine-driven generator is not at all unusual, nor is it, as a rule, objectionable on this type of machines, and there are hundreds of machines operating satisfactorily in this condition. The commutator is finished in the shop after being installed on the armature, but even at that, when the armature is installed on the engine shaft the commutator frequently runs with a slight eccentricity which can best be removed by truing it up while the armature turns in its own bearing.

The operator in this case had tightened the commutator without heating it, and, to make sure that it was tight, applied all the pressure that three men could exert with a six-foot length of pipe on a wrench. The result of this treatment was that the commutator was so tight that the heat due to normal operations caused the commutator bars to bend out in the middle—this caused poor brush contact, and the sparking became worse than ever. By loosening the commutator, heating it and retightening, using the pressure of two men with a two-foot length of pipe on the wrench, and then grinding the surface with a stone, commutation became perfect, although the commutator was still eccentric.

Blowoff Pipe Scaled

The engineer who has no trouble with scale in his boilers is a fortunate individual. The scale-forming salts in boiler-feed water, as is well known, coat the boiler shell and tube, frequently to such an extent that in the case of return-tubular boilers the tube ends become burned and are prevented from leaking seriously only by the heavy deposits of scale around the tube and on the boiler heads. In water-tube boilers the scale problem is so serious in many localities that some of the tubes become practically stopped up with a hardened lime deposit.

FIG. 1. SCALE IN HORIZONTAL PIPE

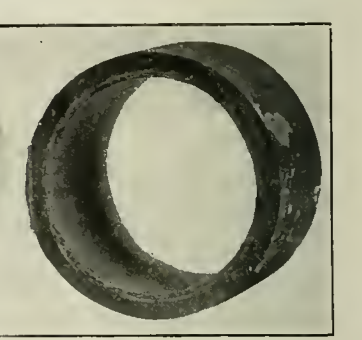

FIG. 2. SCALE IN THE VERTICAL PIPE

The boiler blowoff pipe is not exempt from scale deposit, and sometimes the formation presents an interesting study. For instance, Fig. 1 shows a piece that was cut from the horizontal section of a blowoff pipe on a 72-in. boiler. This pipe had been in use for four years, and the boiler was, so far as known, blown down at least once each day. It is interesting to note the built-up layers of scale, as shown by the variation in colors. Although the inside diameter of the pipe is approximately $2\frac{1}{2}$ in., the opening through the scale is but $1\frac{3}{16}$ in. at its greatest diameter.

In Fig. 2 is shown a piece of the pipe that was cut out of the vertical section, and, as may be seen, the scale formation is but about $\frac{1}{16}$ in. thick, and evenly distributed at that. An interesting question is, Why did the horizontal pipe scale so much more than the vertical section?

What Are You Doing With Your Coal?

THE United States must furnis 634,594,000 net tons of bituminous coal to feed e ever-increasing demand of the war machine for fu and to keep the country warm during the present c year. Estimates compiled by the Fuel Administra n indicate an increased demand for 79,866,000 ne ons of bituminous coal, which must be met either an increased production or by conservation and nitation in the use of coal. To meet this demand full by production would mean an increased output 14.4 per cent. over the production for the year 19 which amounted to 554,728,000 tons.

The estimates are based up figures submitted by the various departments of th Government indicating their increased demands for el during the current year. In some cases the uel dministration has found it necessary to go direcly industrial consumers to ascertain the amount of hei equirements. To secure an output of 634,594,00 to during the coal year it would be necessary to rain n an average weekly production of more than twelv illion tons. This amount has not been producedin y single week during the history of the bitumino al mining industry. The nearest approach to thi r irement was reached during the week of May 25, wh the week's production was estimated at 11,811,00 tons.

The demands for s g ships from American ports on foreign service sh he largest percentage of increase. The Shippi oard has estimated that to supply bunkers to s in the foreign trade will require thirty per ce ore coal than in 1917. The industrial requirem of the country, augmented by the tremendous ex n of war manufactures, will demand eighteen pe t. more fuel during 1918 than during 1917. The ic utilities of the country will need a fifteen per increase, domestic consumers a thirteen per cent rease and the railroads a seven per cent. increase he requirements of last year.

In addition to t increases, new requirements for coal will demand ditional nine million tons. Two million tons of t e allotted as a substitute in the West for oil, wh ay not be available because of ocean transporta ifficulties, and seven million tons will go to give ditional ten days' storage supply to the industri erns and public utilities outside of the New En States. The regular allotment to New England rovide for thirty days additional storage in thos es.

There will b crease in the amounts allowed for exports, for nufacture of beehive coke or for bunkering do ships, including those on the Great Lakes.

The indus onsumption of coal will be about eighteen per greater for this current year than it was last But this presupposes still greater economy in the use of coal than has even now been widely achieved. With the Fuel Administration classifying power plants and giving priority of coal to those that do all they can to economize, engineers must not cease but must increase their vigilance in and about the plant.

No engineer could do better than spend an hour with his chief, going over with him this classification plan of the Fuel Administration. The argument that the matter of power costs is insignificant compared with the cost of the product made at the mill or works no longer holds. Coal is essential, be its cost great or small. To get it in reasonable time a plant must show that it is using it economically. The plant management must *show*—not assert or promise or protest, but show—that it is using it efficiently. Our readers may be sure that the Fuel Administration means business. The coal-mine operators, particularly those of Pennsylvania, have been shown recently, and in a surprisingly forcible manner, that the Fuel Administration means business.

If you keep no account of the performance of your plant, particularly the boiler room, begin to do so immediately. Use as high-class scales and meters as you wish, but use something right away. A record of wheelbarrow or dump-cart or carloads of coal is better than no record at all; but such crude means should be temporary only. The time is here when the management must see the necessity of providing the right selection of meters, instruments and equipment for the plant. Having got them on the recommendation of the engineer, he expects that the engineer knows how best to use them and that he will so use them.

Fires in Turbo-Generators

THERE are numerous ways in which a turbo-generator may fail in service, and for periods of from a few seconds, where the steam end opens inadvertently owing to the overspeed device operating or a mistake on the part of the operator, to several weeks when the generator burns up and must be rewound. The steam end of a turbo-generator causes lesser delays, but more frequent ones than the electrical end. Worn bearings, stripped or eroded blades may be renewed in a few hours. With the electrical end it is usually a different matter, for the trouble, instead of being localized and readily get-at-able, is such as necessitates disturbing parts other than those affected, and much work in reaching them.

The larger the capacity of a machine the greater the dependence placed upon it; the greater the importance, therefore, of maintaining it in service and the more serious its failure. Precautions may be justified with large units that would not deserve consideration with smaller ones, nor would they be financially feasible.

Undoubtedly, the most serious accident that can be-fall a turbo-generator, which is not only the most expensive to repair but also of the most protracted delay, is that of a burn-out. Rarely is but one coil alone damaged, but generally several. Often the core is damaged too, necessitating replacement. In any case taking out and replacing the damaged coils require that other coils also be removed in reaching those injured. As a matter of fact, many coils are usually damaged, if not by the actual short-circuit and accompanying arc, by bending and movement in the slots under the enormous magnetic stresses set up by the short-circuit current. When a generator short-circuits internally, a fire may follow, though not necessarily, and a sustained internal fire may cause a short-circuit, although the cause cannot always be easily determined after the event, since the consequence removes the cause in many cases.

A few years ago, when one of the leading central-station companies installed a large turbo-generator, an occurrence of world-wide interest at that time, the matter of internal fires and possible modes of protection were considered, it being felt by some that the chance of conflagration occurring was a very real one, accompanied by very extensive damage. However, at that time the ruling opinion was that the large modern turbo-generator contained nothing that would burn, and that such machines were amply protected. Since that time several serious fires have occurred in turbo-generators—one in the station already referred to—that resulted in extensive damage to the units involved, heavy expense for repairs and perhaps an even greater cost due to loss of capacity and operating smaller and less efficient machines.

The incidents cited in the discussion letter, "Fires in Turbo-Generators," on page 705 of May 14 issue, clearly indicate that the modern turbo-alternator is far from being fireproof, and if fires do occur they are rarely quenched before the windings are destroyed. Although experiments have been carried on recently, as pointed out on page 883 in this issue, to find out the best method of extinguishing fires in large generators and motors, this subject has not received the attention that it merits, as evidenced by the large number of machines that have been destroyed by fire, with no special means of extinguishing the fire at hand. This seems to be one feature in the design and operation of large electrical machines that, if given the proper attention, holds forth possibilities of greatly increasing the reliability of this class of equipment.

Duty of the Employer in Reconstruction of the Crippled Soldier

ALMSGIVING tends to make the recipient more dependent. On the other hand, if the same individual is provided the wherewithal to earn his own living and made to feel that he is earning it, he will be put in a fair way to achieve success and become an asset to the community. It is with this fact in mind that the American Red Cross has undertaken the reconstruction work for our crippled soldiers, thousands of whom will return from the battlefronts before the termination of the war. The employer's side of this work is clearly outlined in an article, "Duty of the Employer in the Reconstruction of the Crippled Soldier," by W. C. McMurtrie, on page 890 of this issue.

It is well known that our pension system, in so far as constructive ends are concerned, has been a failure. The pension did not provide sufficient means to support the disabled soldier in decency, and instead of arousing in the cripple a desire to help himself, it was an incentive to idleness and, not infrequently, worse. From the experience gained in foreign countries it has been demonstrated that the only sound method of dealing with the disabled soldier is to train him for a trade in which his physical disabilities do not incapacitate him. The work carried on in Europe has shown that it is practically possible to train every cripple in some class of work so as to make him an independent and useful citizen.

The problem of making not only the military cripple but also the industrial cripple useful should be considered, for we cannot afford to allow a healthy man to be a dependent on the nation when a little intelligent effort on the part of an employer might make him a productive worker and an independent citizen.

According to the plan under way in this country, the Government will provide the necessary medical treatment, supply artificial limbs, conduct the training for an occupation and find the job. It will, however, rest with the people whether they will encourage the soldier to accept the advantages of training which will refit him for a life of usefulness and self-respect. There is a general feeling that the nation should maintain the crippled soldier in idleness for the rest of his natural life. Nobody will deny that the disabled soldier is entitled to every consideration, but maintaining him in idleness or in a charity job is generally the last thing that tends toward maintaining him as a self-respecting citizen. As Mr. McMurtrie has pointed out,

> Too many employers are ready to give the crippled alms, but not willing to expend the thought necessary to place him in a suitable job. This attitude has helped to make many cripples dependent. With our new responsibilities to the men disabled in fighting for us, the point of view must certainly be changed. What some cripples have done other cripples can do if only given an even chance. If the employer will do the returned soldier the honor of offering him real employment rather than proffering him the ignominy of a charity job, it will be a great factor in making the complete elimination of the dependent cripple a real and inspiring possibility.

Garabed Giragossian, who was going to pluck energy out of the vast unknown, has failed at this writing to exhibit an operating machine. He told the writer that he has had a machine in operation and has run it from eight o'clock in the evening until two in the morning continuously and many other times for shorter periods; that he can stop and start it any time at will and can demonstrate the practicability of his plan inside of a week after the appointment of the investigating committee. Come on, Garabed, step on the gas!

". . . We have added to the American flag since our war against Germany began, nearly 4,500,000 tons of shipping. We have today under contract and construction 819 shipbuilding ways including wood, steel and concrete, which is twice as many shipbuilding ways as there are in all the rest of the shipyards of the world combined."—*Chairman Hurley of the Shipping Board.*

Indeed the Yanks are coming!

HANDY PLIERS FOR REPL FUSES

Burning Wood to serve Coal

It has been suggested freq of late that we of the Southern States burn wo rder to conserve the supply of coal. I have bee sted particularly in the descriptions of differe ods of burning this fuel. I believe, to be cons that seven-tenths of the steam plants in the St lorida are generating steam with wood as fuel. from the larger plants the same proportion wi rue for the State of Georgia. Alabama, of co nearer to the coal fields and therefore burns m There seems to be a general impression tha uel is plentiful in these three states, but man are burning slabs and strips because cord w her impossible to get or so expensive as to prohibitive, which would seem to indicate that not so plentiful after all.

In my opinion it criminal to waste a thousand B.t.u. in wood l, and the present methods are most wasteful. y economical way of burning wood or slabs, it, or grind it to ¾- or 1-in. size, store in an storage bin and feed directly to boilers e ith dutch ovens. In this way all the fuel recei be hogged, stored and burned as needed. The onomy resulting from an installation of thi uld be a closer regulation and a more unifor combustion, as the fire-doors would not hav ened so often, admitting large volumes of cold air, and less damage would be done to the boiler setting. A motor-driven chain conveyor could be used to deliver the hogged fuel to the firing floor or directly to the furnace.

I would like to see more discussion on wood as fuel. Aside from the reasons why I should burn it, I am interested in any suggestions as to how I can use it to better advantage.

W. Walton Cranford.

Fort Myers, Fla.

Repairs to Broken Gear Wheel

The machine to which a large gear, broken as shown in the illustration, belongs should be in use every day, so when it broke it was up to the master mechanic to make quick repairs, for under present conditions the delivery of a new one or having the broken one welded would mean the loss of valuable time.

We found the web cracked through and the rim partly through at *A*. The hub and arms were broken through at *B* and the rim at *C*, and the gear was forced around on the shaft until the key was about at *X*. We drew the key and removed the wheel from the shaft, then drew the gear together with rods and bolts as closely as possible. Next, three rings were shrunk on the hub, two on one side and one on the other, and plates made to fit the inside of the rim, as shown by the heavy lines. These were drilled and put on with capscrews after the hub was drawn up by the bands. The arms were stiffened by means of rods from the strap *D* hooked over two good arms and on the other side, where the hub was long enough to receive it, by a large band. The gear was then replaced, keyed up tight and the machine started, and it ran as well as ever.

BROKEN GEAR WHEEL REPAIRED AND RETURNED TO SERVICE

Instruments Improve Plant Economy

In the plant in which the writer is chief engineer, two 372-hp. water-tube boilers equipped with chain-grate stokers were installed. One of first questions to arise was that of damper regulation. It was decided to control the dampers from the fronts of the boilers, using straight pieces of shafting and rocker-arms to complete the connection with a ratchet lever mounted at the side of the setting. This arrangement worked satisfactorily until a draft gage, a recording steam-pressure gage and a hand CO_2 outfit were purchased. The recording-pressure gage began to tell tales. Fig. 1 will give an indication of what was happening. The firemen would allow the steam pressure to drop 10 or 15 lb., then open up the feed on the stokers so that a large quantity of green coal was fed onto the grates. They would also open up the damper and allow a rush of cold air into the furnace, lowering the temperature of the combustion chamber as well as carrying 50 per cent. of the volatile gases up the chimney unburned.

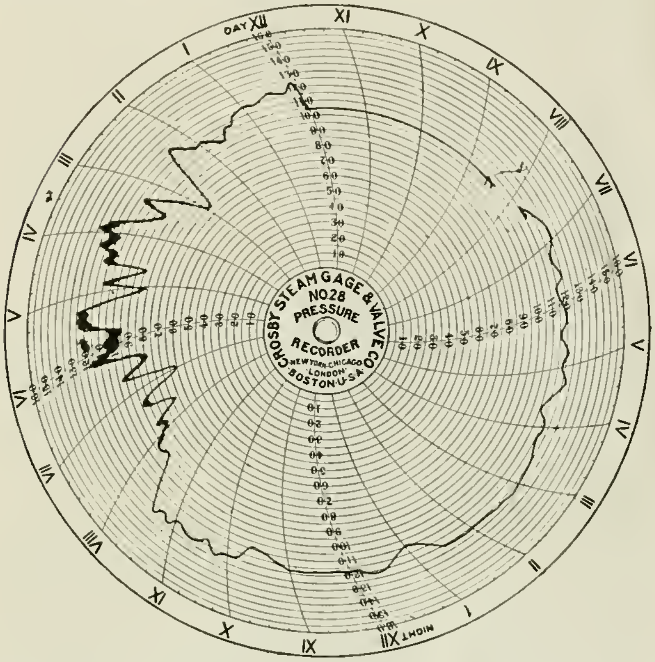

FIG. 1. PRESSURE CHART BEFORE PURCHASE OF INSTRUMENTS

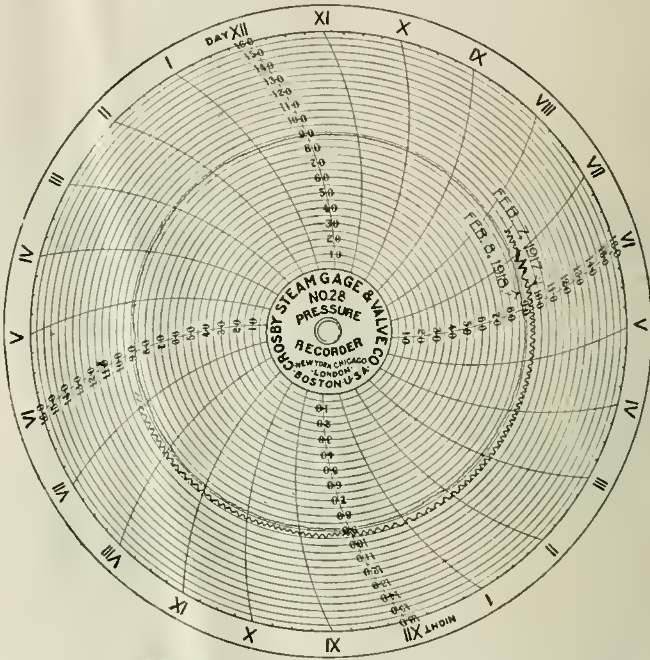

FIG. 2. COMPARATIVE PRESSURE RECORDS TAKEN FEB. 7, 1917, AND FEB. 8, 1918

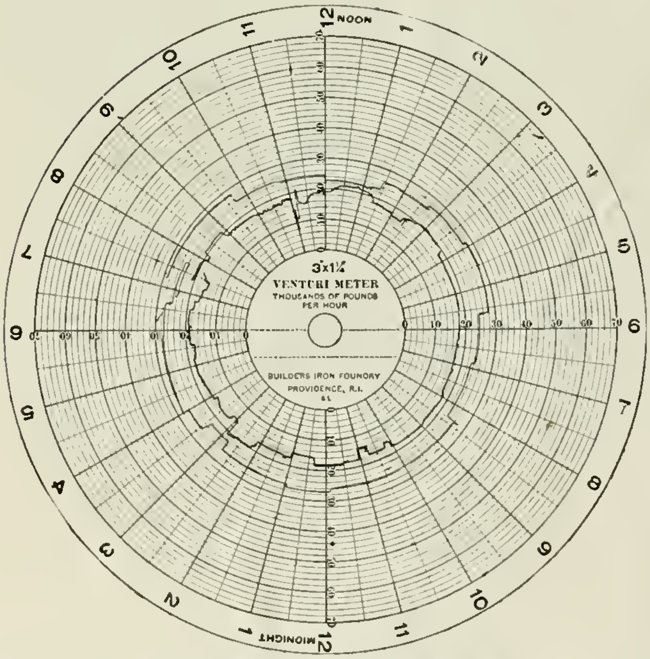

FIG. 3. VENTURI-METER READINGS SAME DAY IN CONSECUTIVE YEARS

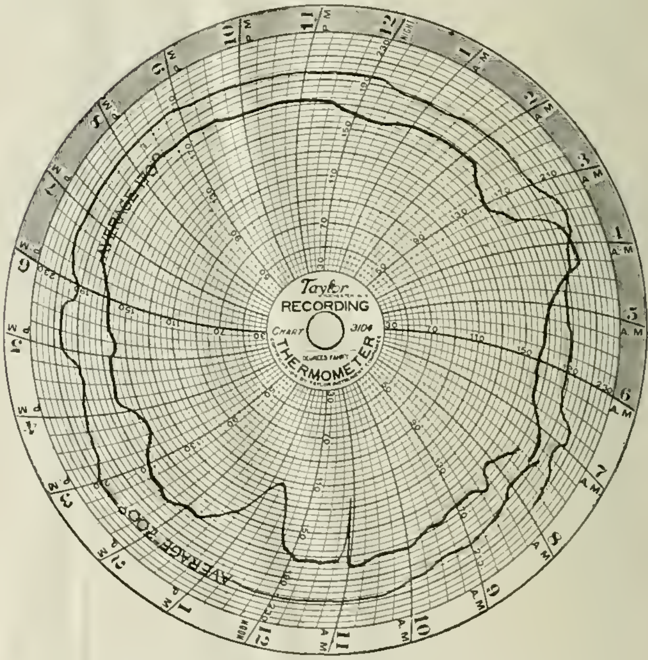

FIG. 4. RECORDING-THERMOMETER CHART, SHOWING INCREASE IN FEED-WATER TEMPERATURE

Instructing the firemen to continue to operate the boilers as they had in the past, I connected up the CO_2 analyzer and took a reading when the combustion was good and the steam pressure normal. The result was 12 per cent. CO_2. When the steam pressure began to drop, the fireman as usual, proceeded to admit a large quantity of green coal and open up the damper. A sample of gas showed only 5 per cent. CO_2. Evidently a change in firing methods was in order to stop the fluctuation in pressure, and it was apparent that the draft was not regulated as it should be.

A damper regulator was purchased and this instrument worked to perfection. Still there was not proper control of the stoker engine. This difficulty was overcome by taking off the governor, putting a ½-in. bypass around the main throttle and opening the valve just enough to keep the engine turning over. An arm from the damper-regulator shaft was then connected to the throttle valve, and the regulator was set to operate at a small variation in pressure. The outer circle in Fig. 2 shows the result of the first attempt, and the inner circle indicates what is now being done in the plant. The variation in steam pressure is very small and the CO_2 seldom goes below 11 per cent.

It is worthy of mention that the recording charts are being conserved by using them from year to year on corresponding days by changing the color of the ink. The records shown in Fig. 2 were taken on Feb. 7, 1917, and Feb. 8, 1918. The plan is not so much to conserve the paper charts as to create comparative records of corresponding days in two or more years, depending upon the number of times the charts are used. This is a great help in operating the plant at high efficiency. Take for example the venturi-meter chart in Fig. 3. It shows how much the load has increased in a year's time, and Fig. 4, a chart from the recording thermometer, indicates the relative feed-water temperatures. The last-named instrument is a great improvement over putting your hand on the discharge pipe of the boiler-feed pump to learn the temperature of the water. Besides, it helps to locate any trouble that may develop in the pump. When the latter begins to give trouble, it is not always easy to tell whether the water is too hot or whether the pump is airbound. With a thermometer there is no difficulty in making the proper decision.

In the plant under discussion the use of a recording thermometer resulted in a considerable saving in coal. It was impossible to get the feed-water temperature above 170 deg. If it could be raised to 200 deg., calculation showed that a saving of $1.83 per day in coal could be effected. The trouble was in the location of the feed-water heater. It had been placed on a dead end from the exhaust heating line, so that there was no circulation through it, and the only way to remove the air was to open the roof valve, which of course was a waste of heat. Remodeling the piping connections so that all the exhaust steam passed through the heater on its way to the heating system made a feed-water temperature of 200 deg. possible, and as shown in Fig. 4, this temperature has been exceeded. J. J. SPANGLER.

Mooseheart, Ill.

Operated Turbine with Stripped Blading

I have read with interest some of the articles in *Power* regarding steam-turbine accidents and I wish to relate an experience due to losing six rows of the low-stage blading on a 500-kw. unit in the plant in which I am employed. The accident occurred with about 40 per cent. load on the turbine just after the generator had been synchronized with another unit and at the time the attendant was building up the vacuum on the condenser.

I was not at the plant when the accident occurred, but arrived about fifteen minutes afterward, and from evidence and from information gathered from the operating engineer I am of the opinion that the stripping of the blading was caused by water being forced up into the low-pressure end of the turbine by the priming pump after the circulating pump had stopped owing to a blown fuse on the motor drive, a jet type of condenser being used.

After removing the stripped and distorted blading from the cylinder and spindle, we put the turbine back in service and operated it for several months before renewing the low-stage blading, being able to pull the full rated capacity of the generator, although at a considerable increase in steam consumption. HOMER I. REEDER.

Emporia, Kan.

Fires in Turbo-Generators

The article "Fires in Turbo-Generators," by M. A. Walker, appearing in the Jan. 22 issue of *Power*, and the letter by Everett Palmer in the May 14 issue commenting upon this article, show conclusively that the problem of extinguishing fires in turbo-generators is one that should cause every power-plant operator serious concern. The number of turbo-generators in this country that have been completely destroyed by fire and that might have been saved with only the loss of one or two coils had the proper facilities been provided to take care of such emergencies, should make both operators and manufacturers consider such protection seriously. These fires have cost thousands of dollars for repairs, and even larger sums due to the long period required to make the repairs, which in many cases require practically rebuilding the whole core and winding of the generator. At first it was thought that the high-voltage turbo-alternator did not contain much that could burn, but today we know by many experiences that short-circuits in these machines will not only cause the insulation to be destroyed, but will also destroy the winding and core themselves.

Recently, a series of experiments was conducted by the General Electric Co., as reported in the January, 1918, issue of the *General Electric Review*, as to the best means of extinguishing fires in high-speed totally inclosed motors and turbo-generators. As a result of these experiments the conclusion was reached that steam, if supplied in sufficient quantities, will put out any fire that may occur by burning insulation; further, that the insulation, if properly dried out after a steam bath, will not be materially damaged. This method has the further advantage of relieving the boilers of some of their steam when practically the whole load of the unit is suddenly thrown off.

Carbon tetrachloride, while not as effective as steam, will put out such fires if used in sufficient quantities. It has the disadvantage, however, that it will attack and destroy the insulation; furthermore, its fumes are very injurious when breathed.

Carbon dioxide seems to be equally effective in putting out these fires, but it is hard to apply. It has to be kept in containers under high pressure, and there are instances where, when these gases were released, the outlet nozzles were quickly frozen up, owing to the refrigerating action.

As pointed out by Mr. Walker and Mr. Palmer, it is necessary that the machine be made dead and disconnected from the line immediately when the trouble occurs, which can probably be best accomplished automatically, after which the steam should be turned on as soon as possible.

Another feature is the ventilating air. This must be cut off and the dampers at both intake and discharge must be closed, for the admission of large quantities of air will have a very marked effect in causing the fire to spread. In my opinion steam is far superior to water for putting out these fires, not only by reason of the advantages already pointed out, but also because the use of water is attended with some uncertainty as regards both its application and its effect on the rotating parts. Steam readily penetrates to all parts of the windings and will readily reach a fire in any remote part of the windings, where it might be impossible to reach it with water unless a considerable quantity is used. B. A. Briggs.

New York City.

Analyses of No. 2 Buckwheat Coal

In the May 21 issue of *Power*, page 728, under the title, "Coals of the United States," are given the proximate analyses of a number of coals from representative districts, the authority being Bureau of Mines Bulletin No. 22.

In the coals listed only one analysis of an anthracite is given. This is reported as being from an anthracite culm, but the results of this one analysis are so good compared with the anthracite received at the plant where I am employed that I ask you to give the inclosed analyses room in your publication so that others may see that all anthracite steam fuel is not as good as the article referred to would indicate. These analyses have not been chosen, but are the consecutive results of occasional samples taken and analyzed by a capable chemist.

* Samples were taken from the supply in the boiler rooms.

Anthracite culm is generally understood to be inferior to No. 2 buckwheat (rice). We are now using about 8000 tons of this No. 2 buckwheat per month, and if we could have the analysis equal that given in the Government bulletin quoted by you, we could do with about seven or eight less cars per month based on the reduction of ash only, not considering the increased efficiency of boiler operation with the better fuel.

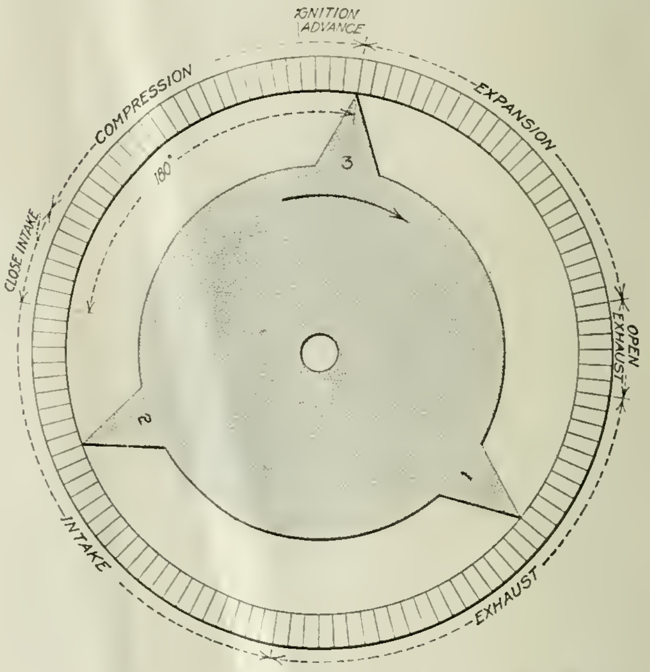
Pottsville, Penn. W. W. Pettibone

Gas-Engine Cycle Indicator

The figure shows a diagram of a cycle indicator for a three-cylinder four-stroke-cycle internal-combustion engine which I designed. To engineers familiar with the cycle the indicator is self-explanatory. The circular scale represents the four strokes of the cycle, or two revolutions of the crankshaft and one revolution of the camshaft. The pointers 1, 2 and 3 on the rotating member represent the cylinders and their working parts.

The pointers are numbered in the firing order of the cylinders, and the center piece must always contain as many pointers as there are cylinders in the engine. The center portion may also be made round and of the diameter of the inner circle of the scale, and in place of the pointers lines may be drawn and numbered accordingly. No matter how many cylinders there may be in the engine, the pointers will always show the relative positions of the vital working parts.

The indicator may be used for practical and educational purposes. If geared to the engine so that the center portion revolves at camshaft speed, the engineer can tell at a glance how the engine stands and what adjustments must be made, and by turning the engine two revolutions every valve and igniter can be set.



FOUR-STROKE-CYCLE, INTERNAL-COMBUSTION ENGINE CYCLE INDICATOR

In looking at the diagram, No. 3 piston stands at top dead-center for ignition. No. 1 and 2 show the position during exhaust and intake respectively. Turning the engine a little farther, No. 2 intake closes with about 36 deg. delay at the lower end of the stroke. A little farther turning closes No. 1 exhaust at the upper end of the stroke. For demonstration purposes the indicator may be used as a hand instrument.

Pittsburgh, Penn. John Fetzer.

Surplus electric power produced by the Stimson Mill Co. at Ballard, Wash., by the burning of waste material will be sold to the City of Seattle at 0.004c. per kw.-hr. The mill company agrees to deliver to the city 1300 kw. for 12 hours and 300 kw. for the other 12 hours of the day.

Inquiries of General Interest

Advantages of Throttling Wet Steam—How is the operation of an engine improved by partly closing the throttle when the supply of steam is from a boiler that is priming? D. W. J.

By partly closing the throttle the process of wiredrawing the steam reduces its pressure, and the heat contained in the initial wet steam is sufficient to convert the mixture into dry steam at the reduced pressure, with the advantages of removing danger of a smash of the cylinder from presence of a large amount of water and of obtaining work of expansion from a larger proportion of the boiler output.

Radial Valve Gear—What is meant by the term radial valve gear? R. G.

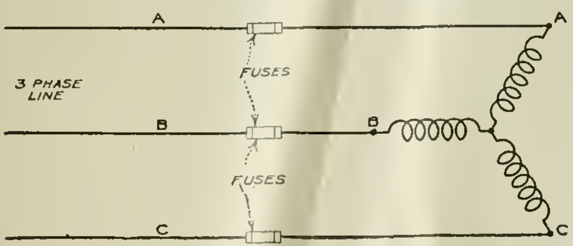
The name radial valve gear has been applied to a number of reversing gears that are quite different in design but agree in deriving the mid-gear motion of the valve from a source that is equivalent to an eccentric with 90 deg. advance combined with another motion that is equivalent to that of an eccentric with no angular advance. The general principle of operation of radial gears is that of obtaining from some reciprocating or revolving piece of the engine, an arrangement of radius bar and link work, a point in which shall describe an oval curve, and by altering the direction of the axes of this curve to produce a valve motion adapted to variable cutoff, reversal or stoppage of the engine.

Diameters of Mating Cone Pulleys—With stepped or cone pulleys used for belt transmission at variable speeds, should the sum of diameters of corresponding drivers and followers be constant for a constant length of belt? F. W.

When the belt is run crossed, a constant length of belt will be required for a constant sum of diameters, but for an open belt of constant length, the sum of diameters of mating steps cannot be constant because there is a changing belt angle to alter the length of belt required. The discrepancy is not perceptible for ordinary lengths of open belts required for countershafts, but for such cases as foot-lathe drives and speed cones, where the cones are closer together and there is a wide difference of diameters, the sum of diameters must be varied to compensate the varying belt angle.

Fuse Blown on 3-Phase Circuit—If one fuse blows on a 3-phase line supplying a 3-phase motor, will the motor be operating 2-phase or single-phase? N. E. A.

If one fuse blows on a 3-phase line that is supplying a 3-phase motor, the motor will then be operating single-phase.



Consider the three lines *A*, *B*, and *C* of the 3-phase circuit in the figure, one phase from *A* to *B*, another from *B* to *C*, and the third from *C* to *A*. Then if the fuse blows in line *A*, the phases from *A* to *B* and *C* to *A* are dead, the one from *B* to *C* being the only one that is alive.

Water Handled by Pump—What quantity of water would be handled by a 14-in. x 36-in. duplex pump making 12 revolutions per minute? J. D.

Neglecting the reduction of cross-sectional area of plungers or water cylinders due to piston rods, the displacement per stroke would be 14 × 14 × 0.7854 × 36 = 5541.78 cu.in. There would be four single strokes per revolution and with 12 revolutions per minute the total plunger or piston displacement would be 12 × 4 × 5541.78 = 266,005 cu.in. or 266,005 ÷ 231 = 1151.5 gal. per min. The actual discharge will depend on the amount of slip or reduction of the amount of water actually handled, due to defective piston packing, leaky stuffing-boxes or valves, the delayed closing of the valves and the amount of air carried into the pump body by the water. For a pump of this size and speed in good condition and working at moderate pressure, the slip should not exceeed 2 per cent., and the amount of water handled should be 98 per cent. of 1121.5 = 1128.5 gal per min.

Conversion of Vacuum Readings to Standard Barometer—If a mercury vacuum-gage reading is 26.5 in. at a temperature of 80 deg. F., with the barometer reading 29.3 in. at a temperature 70 deg. F., what would be the equivalent vacuum with 30 in. barometer at 62 deg. F.? G. A. W.

For practical purposes, and within moderate differences of temperature and barometer, the equivalent vacuum would give the same variation from the barometer; that is, 26.5 in. vacuum with 29.3 barometer might be considered to be equivalent to 30 — (29.3 — 26.5) = 27.2 in. vacuum with 30 in. barometer. When temperatures are considered the coefficient of expansion of mercury may be taken as 0.0001 per degree on the Fahrenheit scale and 26.5 in. of the vacuum gage would be equivalent to 26.5 — [26.5 × (80 — 62) × 0.0001] = 26.4523 in. at 62 deg. F., and the actual barometer reading of 29.3 in. at the temperature of 70 deg. F. would be equivalent to 29.3 — [29.3 × (70 — 62) × 0.0001] = 29.27656 in. at 62 deg. F. Therefore the unbalanced pressure would be 29.27656 — 26.4523 = 2.82426 in. of mercury at 62 deg. F. and used for 30 in. barometer at 62 deg. F. this would be 30 — 2.82426 = 27.17574 in. vacuum.

Estimating Height of Suction Lift—When a pump operates with a suction lift, how can a vacuum gage inserted in the suction pipe at the pump show the height of the pump above the water supply? W. G. S.

Water is forced up in a pump suction pipe by the pressure of the atmosphere acting on the surface of the suction water with sufficient pressure to overcome the inertia and friction of the water entering and moving along the pipe, plus the pressure due to the height of the suction lift, plus the pressure acting on the water at the pump. When a pump moves only just fast enough to keep the water in motion, there will be little pressure lost in overcoming friction and inertia and the atmospheric pressure will have to overcome little more than the pressure due to the height or head of water plus the pressure not removed by the pump.

A vacuum gage connected with the suction pipe at the pump will show how much lower than atmospheric pressure the pump has reduced the pressure at that point and each "inch of vacuum" will represent 0.491 lb. per sq.in. less than the pressure of the atmosphere. A vacuum gage placed at the level of the suction water would indicate 0 inches of vacuum, because the pressure would be equal to the pressure of the atmosphere. When no part of the atmospheric pressure is employed for overcoming friction or inertia of the water (as would be practically the case when a pump is running only just fast enough to "hold suction") then the pressure created by the head of water in the suction pipe would be equal to atmospheric pressure less 0.491 times the "inches of vacuum" at the pump, because the sum of these pressures would balance the pressure of the atmosphere. Atmospheric pressure may ordinarily be taken as equal to 14.7 lb. per sq.in. and, as one foot head of water makes a pressure of 0.433 lb. per sq.in., the height of "suction lift" in feet would be [14.7 — (inches of vacuum at pump × 0.491)] ÷ 0.433.

[Correspondents sending us inquiries should sign their communications with full names and addresses.—Editor.]

Spring Meeting AMERICAN SOCIETY of MECHANICAL ENGINEERS

THE semiannual meeting of the American Society of Mechanical Engineers, held at Worcester, Mass., June 4-7, was the largest spring meeting in the history of the society, the registration reaching one thousand. The opening session was held in the ballroom of the Hotel Bancroft on Tuesday evening. R. Sanford Riley, president of the Worcester Chamber of Commerce and a member of the society, greeted the visitors and introduced His Honor, Pehr G. Holmes, mayor of Worcester, who welcomed them to the city. President Charles T. Main acknowledged the welcome in a few well-chosen words, and Charles G. Washburn delivered an address upon "The Growth of an Industrial City." This was followed by a reception at the Worcester Art Museum, after which dancing and refreshments were enjoyed in the nearby Tuckerman Hall.

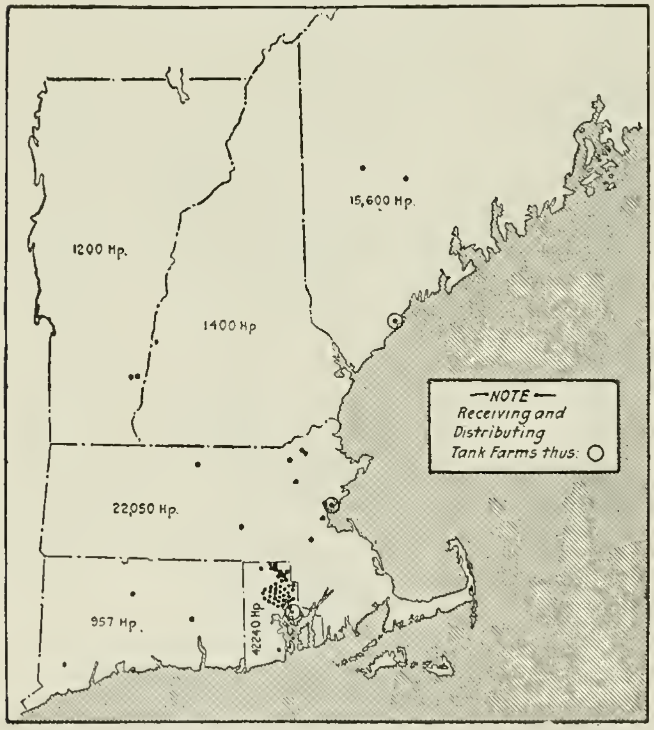


FIG. 1. LOCATION OF OIL-BURNING PLANTS IN NEW ENGLAND

Wednesday forenoon was devoted to a business session in the gymnasium of the Worcester Polytechnic Institute, at which constitutional amendments dealing with the procedure of nominating the officers of the society were considered, and the reports of committees on Screw-Thread Tolerances, Weights and Measures, and Steel Roller Chains were received. Worcester R. Warner delivered an address eulogistic of Past President and Honorary Secretary Frederick Remsen Hutton, and George H. Haynes presented a paper on "The Small Industry in a Democracy." Past President Ira N. Hollis made a plea for consecration to the task of winning the war.

In the afternoon three simultaneous sessions were held in various halls of the Polytechnic Institute. Many of the papers dealt with munitions and other war subjects. That of particular interest to *Power* readers,

OIL FUEL IN NEW ENGLAND POWER PLANTS

by Henry W. Ballou, said that oil fuel was now in use in at least 60 power plants in New England having a total of some 83,000 hp. and in about 100 low-pressure steam plants for supplying heating systems. A list of the power plants and a map of their locations, Fig. 1, are given:

OIL-BURNING POWER PLANTS IN NEW ENGLAND

Plant	Type, Number and Hp. of Boilers	Total Hp.	Year	Oil-storage Capacity, Gal.

About one-half of the boiler horsepower served by oil is in Rhode Island. An outline drawing, Fig. 2, shows a typical power-plant equipment. Insurance requirements have ceased to be burdensome. No difficulty is experienced in pumping oil as warm as 130 deg. F. with a 10-ft. lift. About nine-tenths of these fuel-oil installations are substitutes for coal in existing plants. There is no other method of increasing the capacity of a boiler plant so quickly and cheaply as by substituting oil for fuel. In a number of cases the change to oil has made it possible to shut down one or more boilers. The simplicity and automatic action of oil meters as compared with the cumbersome methods of weighing coal are appreciated, and the keeping of power-plant records is simplified. A few plants have accomplished automatic regulation of the oil feed, but hand control is almost universal. It is inspiring to contemplate the probability that automatic regulation of the oil, the atomizing steam and the draft pressure will become a standard reality within a few years. The saving of labor due to oil firing as compared with coal has been given an exaggerated importance. Other than fixed charges, 80 to 90 per cent. of the boiler-room costs are in fuel, leaving little to be saved in labor. Crude petroleum may be divided into two classes—that with a paraffin base and that with an asphalt base. The first is so valuable for its derivatives that its price will always be prohibitive for fuel. The extremely heavy grades of asphalt-base oils from Mexico are practically the only fuel oils now available to New England. The present rapid increase in their use is but a lucky incident in the marketing of a great natural product. Immense as is its absolute volume, the insignificance of its relative volume as a source of world-wide fuel has thus far been the main obstacle to the adoption of Mexican fuel oil on the high seas. That obstacle is rapidly disappearing and, regrettable though it be, it is inevitable that its very virtues for this purpose will ultimately deprive the power plants of New England of fuel oil.

A commander of the Navy questioned a statement in the paper that the fireman could indulge in naps when fuel oil was used. Greater vigilance and more constant attention to changing conditions were necessary than with coal. Otherwise the fireman would blow oil worth many times his wage up the stack. George H. Diman told of the successful use of oil at the mills of the American Woolen Co., at Lawrence, Mass.

In the evening a general war session was held in the ballroom of the Bancroft, among the speakers being Paymaster C. E. Parsons, of the Navy, and Dr. Irving W. Clark, lately returned from the hospitals in France.

The feature of the meeting of the most interest to *Power* readers was a fuel session held in the gymnasium of the institute on Thursday morning and continued in the auditorium of the Administration Building of the Norton Companies in the afternoon. This will be reported in full in future issues.

Though scheduled to last but two hours, the fuel session continued through the day except for the interval when a most excellent lunch was given the society by the Norton Co. The following topical questions were down for discussion, but so interesting were the papers and the oral discussion that items 1 to 7 were all that could be taken up in the time available:

1. What are the Economic Effects of Impurities in Coal?
2. To What Extent is Fuel Oil Likely to be Used as a Substitute for Coal?

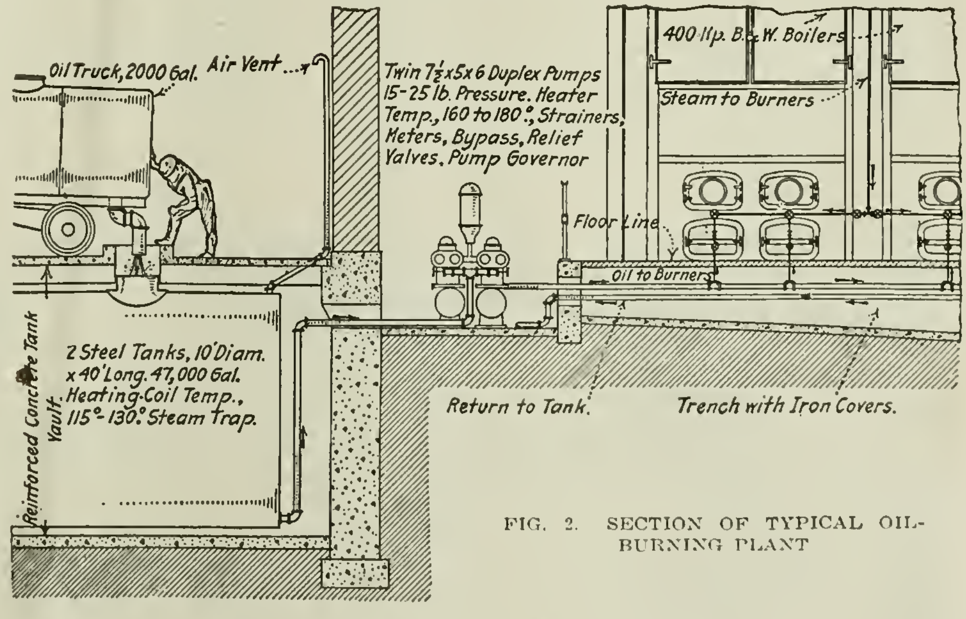

FIG. 2. SECTION OF TYPICAL OIL-BURNING PLANT

3. How Can Soft Coal be Burned Without Smoke in Marine Boilers?
4. What Are the Possibilities in the Direction of the Utilization of Anthracite Wastes?
5. What Instruments Are Useful and Desirable in the Boiler Room as Aids, Etc.?
6. What Is Essential to the Economical Operation of Hand-Fired Boiler Furnaces When Using Soft Coal?

7. To What Kinds of Plants and Coals Are the Different Types of Mechanical Stokers Adapted, and What Is the Limiting Factor to Their Use in Small Plants?
8. What Experience Have you Had in the Use of Wood as Fuel? To What Extent Is Wood Available as a Fuel?
9. What Coal Economies Can be Effected in Residence Heating?
10. What Coal Economies Can be Effected in the Small Steam Plants?
11. What Experiences Have You Had with the Storage of Coal?
12. A Few Additional Topics: (a) To What Extent and Where Will the Gas Producer be Used to Produce Economies? (b) To What Extent Is Natural Gas Being Used as Fuel for Power Purposes? (c) What Is the Relative Economy of the Locomotive of 1900 and Today? (d) What Proportion of the Coke Is Made in Byproduct Ovens? (e) What Are New and Important Developments in Methods of Burning Coal? (f) What Economies Have Resulted from Recent Practice in Making Brick Settings Leakless? (g) To What Extent Is Coke Being Used for Residence Heating? (h) Is Automatic Air Supply Correctly Proportioned to Coal Supply Possible?

The dynamic address of the session was made by E. L. Cole, secretary of the Pennsylvania Fuel Administration, who spoke, following David Moffat Myers, advisory engineer, Fuel Administration, Washington, D. C.

R. J. S. Pigott offered a resolution, which was adopted, in which the Fuel Administration was urged to do its utmost to reduce the impurities in coal. Prof. L. P. Breckenridge presided at the morning session and F. R. Low at the afternoon session.

It is the intention of the society to publish these fuel papers as a supplement to the *Journal;* this will make a valuable publication indeed.

Friday many of those attending the meeting rode out to Camp Deven despite the rain.

New Jersey N.A.S.E. Convention

The convention of the New Jersey State Association of the National Association of Stationary Engineers was held in Perth Amboy, N. J., June 2 and 3. The attendance was unexpectedly large in view of the modest exhibit of engineering equipment and supplies. The new officers are: President, James S. Heath, Elizabeth, N. J.; vice president, Val. V. Secor, Phillipsburg, N. J.; secretary, A. B. Meincke, Newark, N. J.; conductor, Henry Vail, Plainfield, N. J.; doorkeeper, J. Mack, Perth Amboy, N. J. The convention nominated John J. Reddy, the retiring president, for state deputy, Mr. Reddy having so successfully filled that office two years ago. National Secretary Fred W. Raven agreeably surprised the delegates by attending the convention. The association received with acclaim the report of its educational committee, credit for the year's work of which is due chiefly to C. L. Johnson. This committee was voted the usual appropriation. A publicity committee was created, and this work may be performed by the educational committee. A mimeograph machine will be purchased by the educational committee and by this means every member of each association in the state may be provided with study papers issued by the committee.

A resolution of confidence in the Wilson Administration was ordered sent to President Wilson. Another resolution, directed to Commissioner of Labor Bryant, Trenton, N. J., requested him to try to more thoroughly enforce the engineers' license law.

Pleasant entertainment was provided by Bobby Jones and Billy Murray, of Jenkins Bros., and Jack Armour, of *Power.* Next year's convention will be held at Bayonne, N. J.

New York City Electric Rates

The maximum electric rate in Manhattan and the Bronx, New York City, during 1916 was 8c. per kw.-hr. As a result of the activities of the Mayor and the Public Service Commission of New York City, the New York Edison Co. and the United Electric Light and Power Co. reduced their maximum rate to 7½c. on Jan. 1, 1917, and to 7c. on July 1, of the same year. This agreement was reached with the understanding that the Edison companies would continue this rate after a six-months' trial, provided it was found possible to do so, with the prevailing price of fuel, labor, etc.

On June 3, 1918, representatives of the New York Edison Co. and the United Electric Light and Power Co. appeared before the Public Service Commission and announced that the 7c. maximum rate per kilowatt-hour for electric current would be continued after July 1 of this year, despite the fact that the companies have suffered a decrease in revenue due to war conditions. However, the practice of supplying free lamps to their customers is to be abandoned and a minimum charge of 30c. made for the small-sized lamps and more for the larger sizes.

J. W. Lieb, vice president of the New York Edison Co., stated that the operating revenue of the companies had been reduced $941,654 during the first four months of this year, as compared with the same period of last year, and the reduction of the current sold amounted to 4.5 per cent. for the same period. Mr. Lieb said:

> We believe that these conditions would justify the company in going back to the 8c. rate. At the same time it is not absolutely certain that the decrease in output will continue for the rest of the year. We believe that probably the best solution would be a continuance of the present arrangement with the commission, maintaining the status quo for another six months, say, and reserving such rights as we have under the present agreements. This proposal has been accepted by the Public Service Commission.

SOME OF THOSE ATTENDING THE NEW JERSEY N. A. S. E. CONVENTION, PERTH AMBOY, N. J., JUNE 2 AND 3

Western Society Holds Fuel-Supply Meeting

On the evening of June 3 the Western Society of Engineers devoted its attention to the subject of fuel supply. Members of the Coal Conservation Committee of the United States Fuel Administration for Illinois were present to discuss the subject, and they were fortunate to have with them David Moffat Myers, consulting engineer for the Fuel Administration at Washington. Prof. H. H. Stoek, chairman, opened the discussion. From the best information that could be obtained it had been estimated that the additional fuel requirements for this year would be about 15 per cent. An increase of production of 7½ per cent. was the best that could be done, leaving a deficit of 7½ per cent. The plan would be to try and keep all industries going and if need be cut off a little of the fuel supply from each one rather than shut down any of the nonwar plants, as had been proposed at one time. It was of the greatest importance, then, to economize in fuel, and if each coal burner did his part there was a possibility that the deficit would be wiped out.

Mr. Myers Presents the Coal-Saving Plan

David Moffat Myers presented the coal-saving plan that had been prepared recently at Washington, and invited those present to join whole-heartedly in the work. In the past the manufacturer has paid very little attention to the fuel cost and the amount of fuel burned, as it was a very small item in the total cost of production, amounting to 1, 2, 3 or 4 per cent., depending on the product. To make a saving, the manufacturer usually investigated the larger items, including labor, mechanical equipment, raw products, etc., and except where power was the chief product, as in central stations, the power plant received attention last. In order to interest the manufacturer in reducing his fuel consumption, it is necessary to create an incentive, and in the plan now being adopted by many of the states the underlying motive is patriotism. In many cases this will be enough. There are other provisions in the plan to take care of those who neglect to save.

The national plan of organization for fuel conservation in power plants is the result of conference with the United States Fuel Administrators and their committees for a group of states which together consume about 70 per cent. of all the coal used in the country, exclusive of railroads. The plan has been approved also by the United States Bureau of Mines and the committee of consulting engineers on conservation and publicity representing the Engineering Council of the four large national engineering societies. The object is to establish a Government service for the elimination of needless waste of fuel in all power plants, including those in the industries, in office buildings, hotels, apartment houses, etc., and in laying the foundation for the proposed organization, it has been anticipated that this branch of work should become a permanent service of the United States Government.

It has been estimated that 10 to 20 per cent., that is, from 25 to 50 million tons of coal per year, can be saved by the correct operation of steam-power plants, using their present equipment. The effort must be made on this basis, as manufacturing and transportation facilities will not permit of reëquipping the plant. It is considered highly important that all existing fuel conservation committees, committees of chambers of commerce, and national defense, manufacturers' associations and other bodies be continued in full force, and that the work of such organizations be consolidated with the national program. The plan comprises:

1. Personal inspection of every power plant in the country.

2. Classification and rating of every power plant, based on the fairness with which owners of plants conform to the recommendations of the United States Fuel Administration.

3. Responsibility of rating the plant will fall upon the administrative engineers to be appointed by the United States Fuel Administration in each state or district, the rating to be based on information collected by a force of inspectors who will not use their judgment nor express opinions, but merely collect certain definite information included in a questionnaire that has been sent to the plants. After classification and rating of plants according to efficiency of operation, this information will be submitted by the engineer to the state fuel administrator, who shall, in accordance with his judgment, entirely or partly cut off the consumption of coal to any needlessly wasteful plant in his territory. Those plants that follow the recommendations of the Fuel Administration will thus receive the advantage due them for saving coal.

4. Work of the administrative engineers will be to supervise fuel conservation in power plants, including both mechanical and electrical problems connected with the generation and use of steam, power, light and heat, and to supervise the inspection of all power plants in their districts. Inspection will be effected by inspectors of the steam-boiler insurance companies, state factory inspectors, engineering students from technical colleges and volunteers. The rating of each client will be based on the information contained in the questionnaire. Each question will be given a numerical value depending on its relative importance to the other questions, and when the answers are obtained they will be averaged in the same way as an examination paper.

It is further proposed that a standard questionnaire uniform for all states be sent as soon as possible to every power plant in each state or district with notice to the owners that within a certain time, say 60 or 90 days, his plant will be inspected personally and the questionnaire will be checked by the inspector upon his visit to the plant. This action should tend to prepare the minds of plant owners for what will follow and will operate to induce proper care in furnishing the information called for by the questionnaire. It should also create a desire to improve the plants so that they may be rated as high as possible by the time the inspector calls to obtain the information which shall determine the class in which the plant will be rated. The actual rating of plants, however, is to be made by the administrative engineer only after verification and collection of the questionnaires by the inspectors.

Board of Engineers Recommended

In addition to the census of power plants thus obtained it is recommended that a board of competent engineers be attached to the conservation committee in each state in a volunteer advisory capacity to assist the administrative engineer in his work. In addition to numerous other functions, a member of such a board could render valuable service by a personal interview with the owner of the plant that has been given a low rating, pointing out the general causes of inefficiency and aiding the owner in securing the services of a good engineer. Each state should also have available a corps of lecturers who may arouse public interest and disseminate engineering information. To assist in this work the United States Fuel Administration has prepared a fifty-minute film of moving pictures showing good and bad operations in the steam-boiler plant, methods of testing boilers, fuels, etc. The administration is also preparing a series of official bulletins on engineering phases of steam and fuel economics. Also, a list of competent engineers for each state has been prepard in Washington and is available for use by the local administration.

The slogan of the campaign is maximum production with minimum waste. In other words, the object is to operate all industries at full capacity, but at the same time to make a pound of fuel perform its maximum service in power, light and heat.

Dr. F. C. Honnold, fuel distributor of Illinois coal, spoke of the zoning system and how it had affected the distribution of coal from the mines. Illinois had been asked to supply 5,000,000 tons out of the state in substitution for Eastern coal. To do the same work it required from 15 to 25 per cent. more Illinois coal owing to the higher ash and lower heat value. Recently, many Government orders have been placed in the West requiring more fuel for war work, and due to the fact that the Government is going farther and farther west to get smokeless coal for the transports and naval vessels, there will be shortage of coal for Lake movement so that Illinois will have to step in and supply much of the coal to the Northwest.

Primarily, the speaker had been directed to care for railway work first, war work second, and householders third. In purchasing coal, the householders have shown the proper spirit. They have placed orders for their coal promptly as requested, and as a result the mines are shipping more coal for householders than in any previous month in their history. There has been delay in the railway situation. The question of car supply to the mines has not been settled. There are not cars enough to go around to supply fully all the mines. The average provision in the Illinois territory has been 65 per cent. and in the East the supply is considerably less. The price that the railways are to pay for coal will be settled within a few days.

C. W. Naylor expressed impatience over the delay in formulating the plan for coal conservation. He said they had been waiting since January for this plan and to follow it out as outlined would mean such a tremendous amount of work that all the engineers in the country could not carry it out in time to influence this year's consumption of coal. People were ordering coal now, but could not get it. It was his opinion that if the Fuel Administration would spend less time in zoning and in the preparation of such plans as the one presented, and devote more time to loading, shipping and to the car supply, it would be much more to the purpose. The consumer would take care of the coal when he got it.

Osborn Monnett limited his remarks to low-pressure heating, and A. L. Langtry spoke on coal specifications. He referred to Government supervision of all contracts and the restriction that coal companies shall not contract with their customers for more than 65 per cent. of last year's requirements. The Fuel Administration can take the remaining 35 per cent., if needed, and place it somewhere else. Variations in coal last winter had been partly caused by the coal coming from different districts, and not from the same mine. Data were presented to show that in some cases there was wide variation in ash and in others there was very little difference. The tendency, however, is toward more ash and slate, and this is due to mining conditions which have now been corrected.

Educational Work in Iowa

Royal H. Holbrook, of Cedar Rapids, Iowa, spoke of the educational work that had been conducted in that state last winter. A half dozen of the best operating engineers in the state visited every plant that gave them an invitation. Owing to the shortage, it had been necessary to burn more Iowa coal than usual, and it was necessary to teach users how to burn it. In visiting a plant they always called in the owner so that he could learn first-hand the results of the inspection. Their method was to look first for the absence of pipe covering, then to inspect the system and apparatus for cleaning flues, see that the blowoff was working properly and test the setting for air leaks. At the close of the season they had a fairly good record of all plants visited. The weakness was that they could not enforce their suggestions. Next fall they will be ready to start work again to complete the data required by the new Government plan. It was the speaker's opinion that without an immense number of volunteers the Government plan could not be carried out successfully in Illinois. There are 100,000 plants in Chicago alone, and throughout the state there are many more. It is an enormous task and will require the services of a great many competent engineers.

A. Bement was of the opinion that the greatest difficulty would be experienced in the miscellaneous small plants where CO_2 machines were not in favor. A large number of instruments would be required and many difficulties would arise. In his opinion the better plan would be to employ experienced men who could inspect the fire and the plant, diagnose conditions and prescribe the remedy. Not many men would be competent for such work, and if all the combustion engineers in the country were employed they would still be short of help. In explanation Mr. Myers stated that the incentive would be all that was necessary in eight out of ten cases. The mere fact that the plant was to be inspected and its rating determined from the result of this inspection would induce the owner to put it in the best possible condition.

Robert Kuss expressed the opinion that the engineer would come across in the big patriotic way desired and that as soon as the plan goes out he will be ready to back it up. According to estimate it takes 49½ tons of coal to keep one soldier going for the period of a year and with such tremendous requirements as our growing army will impose, it will be necessary for all to give their undivided support to the movement.

Duty of the Employer in Reconstruction of the Crippled Soldier

By Douglas C. McMurtrie

Director Red Cross Institute for Crippled and Disabled Men, New York City

We must count on the return from the front of thousands of crippled soldiers. We must plan to give them on their return the best possible chance for the future. Dependence cannot be placed on monetary compensation in the form of a pension, for in the past the pension system has proved a distinct failure in so far as constructive ends are involved. The pension has never been enough to support in decency the average disabled soldier, but it has been just large enough to act as an incentive to idleness and semidependence on relatives or friends. The only compensation of real value for physical disability is rehabilitation for self-support. Make a man again capable of earning his own living, and the chief burden of his handicap drops away. Occupation is, further, the only means for making him happy and contented.

Soon after the outbreak of hostilities the European countries began the establishment of vocational training schools for the rehabilitation of disabled soldiers. They had both the humanitarian aim of restoring crippled men to the greatest possible degree and the economic aim of sparing the community the burden of unproductivity on the part of thousands of its best citizens. The movement had its inception with Mayor Edouard Herriot, of the City of Lyons, France, who found it difficult to reconcile the desperate need for labor in the factories and munition works while men who had lost an arm or a leg but were otherwise strong and well were idling their time in the public squares. He therefore induced the municipal council to open an industrial school for war cripples which has proved the example and inspiration for hundreds of similar schools since founded throughout France, Italy, Germany, Great Britain and Canada.

The disability of some crippled soldiers is no bar to returning to their former trade, but the injuries of many disqualify them from pursuing again their past occupation. The schools of training prepare these men for some work in which their physical handicap will not materially interfere with their production.

The education of the adult is made up largely of his working experience. The groundwork of training in his past occupation must under no circumstances be abandoned. The new trade must be related to the former one or be, perhaps, an extension or specialization of it. For example, a man who had done manual work in the building trades may by instruction in architectural drafting and the interpretation of plans be fitted for a foreman's job, in which the lack of an arm would not prove a serious handicap. A trainman who had lost a leg might wisely be prepared as a telegraph operator, so that he could go back to railroad work, with the practice of which he is already familiar. Whatever training is given must be thorough, for an adult cannot be sent out to employment on the same basis as a boy apprentice. He must be adequately prepared for the work he is to undertake.

The one-armed soldier is equipped with working appliances which have supplanted the old familiar artificial limb. The new appliances are designed with a practical aim only in view; they vary according to the trade in which the individual is to engage. For example, the appliance for a machinist would be quite different from that with which a wood turner would be provided. Some appliances have attached to the stump a chuck in which various tools or hooks can interchangeably be held. The wearer uses these devices only while at work; for evenings and holidays he is provided with a "dress arm," which is made in imitation of the lost natural member.

An important factor in the success of reëducational work is an early start, so that the disabled man shall have no chance to go out unemployed into the community. In even a short period of exposure to the sentimental sympathy of family and friends, his "will to work" is so broken down that it becomes difficult again to restore him to a stand of independence and ambition. For this reason, therefore, the plan for his future is made at as early a date as his physical condition admits, and training is actually under way before the patient is out of the hospital.

In the readjustment of the crippled soldier to civilian life, his placement in employment is a matter of the greatest moment. In this field the employer has a very definite responsibility. But the employer's duty is not entirely obvious. It is, on the contrary, almost diametrically opposite to what one might superficially infer it to be The duty is not to "take care of" from patriotic motives, a given number of disabled men, finding for them any odd jobs which are available, and putting the ex-soldiers in them without much regard to whether they can earn the wages paid or not.

Yet this method is all too common. A local committee of employers will deliberate about as follows: "Here are a dozen crippled soldiers for whom we must find jobs. Jones, you have a large factory; you should be able to take care of six of them. Brown, can you not find places for four of them in your warehouse? And Smith, you ought to place at least a couple in your store."

Such a procedure cannot have other than pernicious results. In the first years of war the spirit of patriotism runs high, but experience has shown that men placed on this basis alone find themselves out of a job after the war has been over several years, or in fact, after it has been in progress for a considerable period of time.

A second weakness in this method is that a man who is patronized by giving him a charity job comes to expect as a right such semigratuitous support. Such a situation breaks down rather than builds up character, and makes the man progressively a weaker rather than a stronger member of the community. We must not do our returned men such injury.

The third difficulty is that such a system does not take into account the man's future. Casual placement means employment either as a makeshift job as watchman or elevator operator such as we should certainly not offer our disabled men except as a last resort—or in a job beyond the man, one in which, on the cold-blooded considerations of product and wages, he cannot hold his own. Jobs of the first type have for the worker a future of monotony and discouragement. Jobs of the second type are frequently disastrous, for in them a man, instead of becoming steadily more competent and building up confidence in himself, stands still as regards improvement and loses confidence every day. When he is dropped or goes to some other employment, the job will have had for him no permanent benefit.

Twelve men sent to twelve jobs may all be seriously misplaced, while the same twelve placed with thought and wisdom and differently assigned to the same twelve jobs may be ideally located. If normal workers require expert and careful placement, crippled candidates for employment require it even more.

The positive aspect of the employer's duty is to find for the disabled man a constructive job which he can hold on the basis of competency alone. In such a job he can be self-respecting, be happy, and look forward to a future. This is the definite patriotic duty. It is not so easy of execution as telling a superintendent to take care of four men, but there is infinitely more satisfaction to the employer in the results and infinitely greater advantage to the employee. And it is entirely practical, even in dealing with seriously disabled men.

A cripple is only debarred by his disability from performing certain operations. In the operations which he can perform, the disabled man will be just as efficient as his nonhandicapped colleague or more so. In the multiplicity of modern industrial processes it is entirely possible to find jobs not requiring the operations from which any given type of cripples are debarred. For such jobs as they can fill the cripples should be given preference.

Thousands of cripples are now holding important jobs in the industrial world. But they are men of exceptional character and initiative and have, in general, made their way in spite of employers rather than because of them. Too many employers are ready to give the cripple alms, but not willing to expend the thought necessary to place him in a suitable job. This attitude has helped to make many cripples dependent. With our new responsibilities to the men disabled in fighting for us, the point of view must certainly be changed. What some cripples have done, other cripples can do if only given an even chance.

The industrial cripple should be considered as well as the military cripple, for in these days of national demand for the greatest possible output there should not be left idle any men who can be made into productive workers. With thoughtful placement effort, many men can be employed directly on the basis of their past experience. With the disabled soldiers who profit by the training facilities the Government will provide, the task should be even easier.

This, then, constitutes the charge of patriotic duty upon the employer: To study the jobs under his jurisdiction to determine what ones might be satisfactorily held by cripples; to give the cripples preference for these jobs; to consider thoughtfully the applications of disabled men for employment, bearing in mind the importance of utilizing to as great an extent as possible labor that would otherwise be unproductive; to do the returned soldier the honor of offering him real employment, rather than proffering him the ignominy of a charity job.

If the employer will do this, it will be a great factor in making the complete elimination of the dependent cripple a real and inspiring possibility.

Meeting of National Coal Association

At the opening of the first annual meeting of the National Coal Association in Philadelphia, on May 28, the principal address was made by J. D. A. Morrow, Director General of the United States Fuel Administration. The following excerpts are taken from his address:

Every country that has gone into this war has promptly found itself faced with a difficult coal problem. In Great Britain, within six months after war had been declared, 250,000 coal miners had enlisted, and the production in Great Britain fell off 25,000,000 tons. The railways were congested with traffic, and the country faced an industrial crisis.

The important French coal fields were overrun by the enemy at the outset of the war, and production was cut squarely in two. The supply there has been cruelly short, and every pound has been distributed by the government. That has been the case also in Italy.

Thus it is nothing unusual for us to have a coal crisis in this country. You are all familiar with the insatiable demand for coal that coincided with congested traffic on our lines, and within six months after the declaration of war the United States had set up a Federal Fuel Administration, the industry was under Governmental control, and we had followed to that extent at least in the footsteps of other important belligerents.

When I took up the work of directing the distribution of coal, it appeared to me that one of the first things we needed to know was what the requirements for coal would be. To get that information we obtained reports from more than 100,000 industrial concerns, stating the exact quantity they consumed yearly. We obtained reports from 40,000 retail dealers covering their annual deliveries. We obtained reports from the Shipping Board, the War and Navy Departments, and from other Government sources, regarding the building of new factories and extensions to old ones, and the increase of activity in other plants. We also called upon private sources of information. When we had those figures together, we found that to run the United States on a war basis this year we need 735,000,000 net tons of coal.

It seems likely that the production of anthracite cannot exceed the output of the past year, namely 89,000,000 gross tons. The difference must be made up out of the bituminous mines. The bituminous mines of the United States this year are called on to produce 85,000,000 more tons than they produced last year, which was a record year.

Under these circumstances, then, we clearly and definitely face the prospect of a slight shortage of coal this year. Under these conditions we are trying to see that the domestic consumer is taken care of; that the supreme important users of coal get their supplies, and that if any is left that can go to the less important consumers there is where it will go.

In order to make sure that an equitable distribution is had between these important branches we have to get some very definite information about where the coal is going. We intend to require every industrial consumer of coal in the United States to register and to report weekly his exact amount on hand, his consumption, his receipts and the amount that is moving to him. If we have all this information it will enable us to act intelligently; for we will know, at any time, how any given plant or industry or section of the country stands with respect to its coal supply, and it will then be possible to prevent trouble before it occurs in many instances, rather than to try to cure it afterward.

Distribution Division of Fuel Administration

The Fuel Administration is organizing a conservation division which is to inspect the plants and teach the users of coal better methods of burning it in order that tonnage may be saved. It is estimated that if this can be done on a large scale this year it will be possible to save perhaps 20,000,000 tons of coal. Unless this is done many plants necessarily will be without coal and to some extent will have to curtail operations.

I want to make it clear that the Distribution Division of the Fuel Administration intends to be sufficiently in control of the situation to make sure that the domestic consumer gets his supply, that the railroads have theirs, and that the important war plants are all running, and that our ships get back and forth across the Atlantic. If we do that, if we take care of the domestic consumer and keep these plants running, it will be possible for us to avoid the suffering that occurred last winter and the working machinery of the United States will not lose one single stroke for lack of coal.

The zone system of distribution has proved beneficial to the railroads. The vice president of the Norfolk & Western R.R. gives some idea of how it is helping that road. He says: "A comparison of the movement of loaded coal cars in our coal districts during the seven-day period, May 4 to 10, 1918, to determine the advantages derived from the zone regulations, indicates that there was a saving in loaded car mileage in coal fields of 15.2 per cent. or 6982 loaded car-miles in seven days. This is simply the saving of car miles in the coal regions on our lines and does not take into account the saving that has been effected between the origin zones and the points of destination by the elimination of cross hauls."

This is indicative of the important saving in transportation that was effected by the zoning of coal. That zoning no doubt interfered with customary trade relations, it interfered with the customer in getting his supplies. We have this evidence of the fact that the sacrifices made have greatly helped our transportation problem at a time like this, when that is all-important.

To date we have been most admirably supported by the coal men themselves. There have been times when we have made mistakes, made lots of them; we will probably make a good many more. Nobody knows everything about the coal business nor even a small part about all of it, but we are trying to get together in Washington a personnel of leaders in this business in positions of responsibility, men that the coal industry can follow with confidence and respect.

We now understand that for modern war to be anywhere near successful the armies in the field must be supported by equally effective and magnificent war machines built up in the industrial life of the country behind the armies. Germany had exactly that kind of an industrial machine completed before ever this war began.

It is equally necessary for us to build up here an industrial war machine that will support our military war machine just as effectively as does Germany's. Just as the soldier has to subordinate his wishes to the general plan, so the coal man will find it necessary in many respects to lay aside personal desires and privileges and submit his wishes to the general plan for the industry as a whole in support of the war program.

Engineers Wanted for the Army

Engineers are once more in demand for officers in the army. For the last six months or more all applicants for engineers' commissions have been met with the statement that the quota was full and that except for special work, generally at the direct request of General Pershing, no more commissions would be given in the engineers to men now in civil life. Such vacancies as would exist were to be filled by promotions of men already in the service. Our enormously increased army, both in being and in prospect, has changed all this. Under date of June 3, Gen. W. M. Black, Chief of Engineers, U. S. A., issued a call for approximately 2000 additional first lieutenants and captains in the Engineer Reserve Corps, to be immediately commissioned, sent to training camp and as soon as possible thereafter sent overseas to the Expeditionary Forces.

Qualification restrictions are mainly those of age. There are no commissions available in the grade of major or higher or in that of second lieutenant. The higher grades will be filled by promotions of well-qualified men now nearly a year in the service, the lower grades will be filled from the ranks or from the recent college graduates, members of the Engineer Enlisted Reserve. The age limits are 32 to 36 years for first lieutenant and 36 to 42 years for captain. These limits may be slightly increased, or decreased, in certain cases, except that no one within the draft age will be considered.

No set rules as to professional qualifications and experience have been established, except that the applicant must be engaged in the active practice of the engineering profession, in one of its various branches. An examining board will pass upon the candidate's fitness.

All applicants accepted by this examining board will be commissioned within a week or ten days of the examination and a few days thereafter will receive orders to report at an Engineer Officers' Training Camp, either at Camp Lee, Petersburg, Virginia, or Camp Humphries, Virginia, just down the Potomac from Washington. After a course of training in military engineering, they will be assigned to duty with the engineer troops for eventual service abroad. The commission is not final, however, because a candidate may in camp prove not to have the necessary qualities of a military leader. In such a contingency he will be honorably discharged. Each man's case will be carefully considered just previous to the completion of his course of instruction by a board of officers of the Corps of Engineers, U. S. A.

The Government will allow traveling expenses at the rate of 7c. per mile to applicants who may be commissioned, and they will also receive while in training camp the full pay of an officer of their rank. They must provide themselves with the usual Engineer Officer's uniform outfit while at camp.

Applications for these commissions should be made as soon as possible to the office of the Chief of Engineers, Washington, D. C. The office will send back a series of blanks to be filled out with a general personal description designed to indicate the fitness of the applicant for a more searching examination in person by the examining board Those selected will be notified when and where to appear before the board for the further examination.

Chicago's Technical Men Unite for War Work

Representing an effort to coöperate effectively and vigorously for war work, an important joint war committee has been formed by representatives of technical societies centered in Chicago. The movement was started by the Military Committee of the Western Society of Engineers, and, at the invitation of that committee, several meetings have been held at the Chicago Engineers' Club. As the result, the "War Committee, Technical Societies of Chicago," to quote the official name, was organized June 4, 1918.

The purpose of this organization is "to enable the technical societies of the Chicago zone to call into play the efforts of the members of the various societies herein represented as occasion may arise, and to coördinate their activities in the most effectual manner to help win the war." It is not intended to attempt any novel "stunts," but rather to place at the disposal of the United States Government, and other authorized agencies, the combined strength and resources of the Chicago technical societies for war work, as need may arise.

The following member societies are coöperating in the new War Committee: Western Society of Engineers; Structural Engineers' Association of Illinois; Society of Industrial Engineers; Illinois Society of Engineers; Illinois Society of Architects; The American Railway Engineering Association; The Swedish Engineers' Society of Chicago; Illinois Chapter, American Institute of Architects; Chicago Section, American Society of Mechanical Engineers; Chicago Section, American Institute of Electrical Engineers; Chicago Section, American Chemical Society; Chicago Section, American Institute of Mining Engineers; Mid-West Section, Society of Automotive Engineers; Illinois Association of American Society of Civil Engineers; Chicago Section, American Society of Heating and Ventilating Engineers; Chicago Section, American Society of Refrigerating Engineers; Chicago Section, Steel Treating Research Society; Chicago Section, Illuminating Engineering Society; and Chicago Chapter, American Association of Engineers.

Officers of the War Committee have been elected as follows: Chairman, F. K. Copeland; vice chairman, W. L. Abbott; secretary, Edgar S. Nethercut; treasurer, William A. Fox. The executive committee consists of F. K. Copeland, W. L. Abbott, William Hoskins, C. A. Keller, Charles E. Lord, C. F. Loweth, Isham Randolph and Richard E. Schmidt. The address of the secretary of the War Committee is 1735 Monadnock Block, Chicago, Ill.

Largest Smokeless Powder Plant in the United States

The largest smokeless powder plant in the United States, known as "Old Hickory," located near Nashville, Tenn., and building by the du Pont Engineering Co., at a contract price of one dollar, has swung into line back of our boys "over there."

The first sulphuric-acid unit has already been started, and the progress which this marks assures the delivery of powder before July 1, three months ahead of the original schedule, in quantities sufficient to keep a steady flow going to the battlefront in France.

This marks the first completed step of a monumental task which sets a record for engineering and construction work in the United States. The original contract with the United States Government for the building of this plant was signed with the du Pont Engineering Co. on Jan. 29 of this year. It called for a daily output of 500,000 lb. of smokeless powder with the first unit to operate in eight months, or Oct. 1, succeeding units, four in number, to come into commission every six weeks.

On Mar. 23 a new contract was entered into which turned the plant over to the du Pont Engineering Co. as contractors for the Government. Under its terms the contractors were to construct a plant based on their knowledge and experience complete in every detail to turn out 900,000 lb. of powder a day. Under this new arrangement the contractor agreed to bring the first unit into operation on Aug. 1, two months ahead of the previous schedule, and to bring the other units in thirty days apart.

Under this final plan the contractors agreed to do the construction work for a consideration of one dollar. This work included giving to the Government the benefit of all the du Pont skill and knowledge in the design and construction of powder plants gained through long years of actual operating and exhaustive experimental work, and rendered all the more valuable because of the experience gained in the building of modern war plants to supply the powder demands of the Allies before this country entered the war.

With the freedom of action obtained under the final contract, such rapid progress was made that two months ago, when the powder situation became acute, the contractors promised the Government to again put forward the schedule and to produce powder on July 1, bringing into operation the successive units twenty-five days apart. To meet this schedule it would have not been necessary for the sulphuric-acid plant, which started June 1, to have been put in operation for another ten days, so that there is every prospect that some additional time may be saved even on the close schedule finally adopted.

Each one of these units is practically complete within itself and is approximately eight times the size of the largest smokeless-powder plant in the United States prior to the war. The entire plant is approximately seventy times the size of the largest smokeless powder plant in the United States prior to 1914.

There will be a complete power plant for generating electric power and steam. This plant will have eight stacks, 15 ft. in diameter and 200 ft. high.

The plant will consume 4500 tons of coal every operating day of twenty-four hours. This is equivalent to 100 carloads or two trainloads. The completed plant will require 100,000,000 gal. of water every twenty-four hours, or as much water as is used by a city of 1,000,000 population; 65 per cent. of this water must be treated and filtered. The central power plant will contain 68 boilers, each with a rating of 825 hp. These will be operated at an overload, developing approximately 90,000 boiler horsepower, supplying steam for generating 12,000 kw. of electrical power as well as steam power for the treatment of guncotton and other purposes.

In addition to the railroad which is built into the plant, it was necessary to reconstruct the highways leading from Nashville, and within the plant itself many miles of standard railroad track and narrow-gage lines are in operation. The finished plant will contain approximately 33 miles of broad-gage track and 46 miles of three-foot gage track for narrow-gage locomotives and cars.

Wisconsin Modifies Second-Hand Boiler Ruling

It has come to the attention of the Industrial Commission that several manufacturers of this state have found it difficult to obtain new boilers to assist in increasing the production of the factories, and this condition is the result of the scarcity of steel plate which is largely being used in the manufacture of war materials. Consequently, buyers are obliged to make use of second-hand boilers.

With this in mind, the commission at its last regular meeting, May 20, 1918, voted to modify until further notice Order 4208, page 12, Code of Boiler Rules, to the extent that it will be satisfactory to admit for operation with a factor of safety of (5) any second-hand boiler whose longitudinal seam is of the butt type and with double covering plates, with the understanding that the boiler does not conform strictly to all the requirements of Part III of the rules which apply to boilers installed after July 1, 1916.

For example, a second-hand boiler as described may be a trifle short in bracing; have only single lugs for support; blowoff pipe 4 in. in diameter; manholes smaller than required on new boilers; or it may have a dome which would not conform to Order 4348.

Illinois State Convention N.A.S.E.

On June 5-7 the Illinois State Association of the National Association of Stationary Engineers held its fourteenth annual convention at Ottawa. Owing to the busy times, when the engineer in particular must be on hand to keep the wheels going, the number of delegates and visitors attending was less than usual, and although about the same number of booths had been taken, the exhibits were few and none of them elaborate, due to overcrowded transportation facilities and the rush of war work. Headquarters and the exhibit hall were at the Clifton Hotel and the business sessions of the convention were held in the K. of P. Hall.

At 2 p. m. Wednesday W. F. Kirschenberg called to order the first session of the convention. Rev. C. A. Briggs, Jr., opened with prayer. Mayor E. F. Bradford extended an earnest and cordial welcome and presented a large gilt key giving access to anything in the city. He said that he had been impressed by the aims and objects for which the association had been formed. that the idea was splendid and should bear fruit in these times when efficiency in the power plant meant so much. He expressed the hope that their stay would be so pleasant and profitable that Ottawa would be their favorite convention city.

DELEGATES AND THEIR GUESTS ATTENDING THE FOURTEENTH ANNUAL CONVENTION OF THE ILLINOIS

In his response John F. McGrath expressed the appreciation of the delegates for the kind reception. He dwelt briefly on the educational features of the association and on the wonderful success of the lantern-slide lectures. The organization tried to keep the men abreast of the times, not only mechanically but socially as well, so that they might feel that they were on an equality with men in any walk of life.

Joe O'Connell was always pleasantly impressed by the fact that public men such as the mayor or the governor never failed to recognize the value of the engineer to the community. They were students of human nature and understood the engineer better than most other men. With water-works, lighting and power plants of all kinds, street railways, locomotives and marine plants under their control, the engineer had it in his power to create terrible hardships, if he so willed and organized for that purpose. To the credit of the profession the present organization had been formed for fraternal and educational purposes.

J. F. Farrell, ex-mayor, referred to the previous convention in Ottawa and expressed the wish that it might become a permanent issue to meet in the city every year. Upon request the speaker read a paper on "Economy of Coal and Fuel Conservation," by C. W. Naylor, who had been unable to attend. It was Mr. Naylor's contention that in one way the present war was a blessing. It had opened the eyes of the people to the fuel situation and the need for economy in this natural resource. During the coming year it would be impossible to increase much if any, the output of coal. Consequently the user must secure greater economy, the mines must be kept busy the year around and the coal be equally distributed in accordance with the needs. Each individual must wake up to the situation. The householder will be forced to burn mostly Illinois coal and it was up to him to order it now instead of waiting with the hopes of getting anthracite or Pocahontas. Reference was made to ways of saving, such as the elimination of needless lights, shorter working days for those engaged in nonwar work and rigid economy in the power plant. It was possible to get help from the fuel administration. Lecturers were to be sent all over the state and there would be men and literature to show how to burn Illinois coal. To help win the war Mr. Naylor urged general storage of fuel during the summer months and made a special plea to the engineer to spread the gospel of fuel conservation.

Lee O'Neil Browne, an honorary member of the association and the representative of the state legislature who had twice helped the engineers in trying to put through a license bill for Illinois, spoke briefly. He referred to the previous convention at Ottawa eight years ago when he had become a member, and to the great help certain engineers had given him in a boiler explosion case in Lee County. He reviewed the efforts made to pass the license bill against the opposition of certain labor organizations in Chicago and sawmill and other small interests in the southern part of the state. In the second attempt the bill had been passed in both the House and the Senate, but had been vetoed by the governor for the averred reason that it contained too many restrictions. In his opinion the bill could be passed again, but before it reached the governor there would be need of concerted effort to arouse public interest and to create a demand backed by powerful influences that could not be overlooked.

With the official opening of the convention and appointment of committees by John F. Alt, state president, the session closed.

In the evening the exhibit hall in the Clifton Hotel was opened officially, with J. F. Alt presiding. Short talks were made by Messrs. Thayer, Fiske, Lane, McGrath and Roberts on the educational advantages offered by the exhibits. The latest equipment, or literature dealing with it, was on display and valuable information could be obtained from the various salesmen.

Thursday morning the session was given over to routine business and reports. The secretary-treasurer's statement disclosed a comfortable working balance and a net loss in membership of 23 for the state. Mr. Roberts, of Cleveland, a member of the National License Committee, discussed the possibilities of eventually passing the Illinois bill. He thought the conditions favorable. Recent experience showed what must be overcome and they were fortunate in having a representative who had their interests at heart. The speaker warned against trying to get all that was wanted in the bill. It would be policy to get the best bill possible on the statute books and after that amendments would be comparatively easy. To be constitutional the bill must have uniform application throughout the state and there should be no restrictions as to qualifications of the chief examiner. It would be better to let the appointive power assume the responsibility. Sources of objection could be eliminated by giving without further examination, state licenses to men who already possess a city license and to engineers who have been operating for a certain period and can verify it by a statement from their employers. One of the causes of the veto of the last bill was the exemption clause expressing the limit below which a license would not be necessary, in square feet of heating surface rather than in horsepower. To the layman the former meant nothing while all were familiar with the horsepower.

Mr. Roberts had a pamphlet giving proper information to bring before the public and a skeleton bill after the Massachusetts and Ohio plans which might serve as the fundamental basis for the Illinois bill. Incidentally, the national license committee in conjunction with the national president, had decided to limit their efforts to those states where the possibilities of license legislation were most favorable. For 1918-19 Illinois and Kansas had been selected.

Thursday afternoon the entire delegation had a most pleasant outing at Starved Rock State Park, getting back in time to attend the smoker that evening at the headquarters hotel. The latter was a most enjoyable affair and the best attended session of the convention. With Fiske as toastmaster the program was conducted with despatch. Patriotic talks by President Griggs, of the Chamber of Commerce, and ex-Mayor Farrell were interspersed with songs by the audience. John Lane responded and in brief talks was followed by T. W. Roberts, W. E. Hill and Charlie Fiske. Mob singing led by Tilley and dancing were the final features.

At the Friday morning session, State Deputy Hill spoke of the difficulty all organizations have in holding their membership during war times. The draft and enticing positions opened up by the Federal Government were responsible and it required a great deal of intensive work for an association to hold its own.

In the discussion on educational work, Messrs. Hill, Misostow and Harris emphasized the difficulty the state body had in learning what the smaller associations needed. Lectures suitable for locals in large cities often were not appropriate for towns where the membership did not exceed 20 or 30. Questions and answers and traveling lecturers had been tried and in numerous cases did not seem to meet the requirements.

In choosing the officers, John F. Alt and J. E. Noden were reëlected as president and vice president, respectively. On account of war work Gus Anderson was replaced by W. E. Hill as secretary-treasurer and M. E. Harris was recommended for state deputy. The officers were installed by Past Presidents Parker and Misostow. The selection of a convention city was left for later determination by the president and secretary.

The following firms had space in the exhibit hall: Anchor Packing Co., V. D. Anderson Co., W. A. Blonck & Co., Crandall Packing Co., Dearborn Chemical Co., Garlock Packing Co., Hawk-eye Compound Co., Hays Instrument Co., Jenkins Bros., H. W. Johns-Manville Co., Lunkenheimer Co., National Atomizer Co., *National Engineer*, Perolin Co. of America, Wm. Powell Co., *Power*, S. C. Regulator Mfg. Co., Rhodes Metallic Packing Co., John A. Roebling Sons Co., United States Rubber Co., Thayer & Lynn, Tilley-Gillette Co.

STATE ASSOCIATION OF THE NATIONAL ASSOCIATION OF STATIONARY ENGINEERS AT OTTAWA, ILL.

Bituminous Coal Consumption

Following is a statement by the Fuel Administration on coal consumption and requirements. Note the large increase in coal required by industrial plants.

ESTIMATED CONSUMPTION OF BITUMINOUS COAL IN THE UNITED STATES IN 1917 AND REQUIREMENTS FOR 1918–19, IN NET TONS

	1917 Tons	1918–19 Tons	Per Cent. Increase 1918–19 Over 1917
Industrial	204,907,000	242,024,000	18
Domestic	66,915,000	75,678,000	13
Gas and electric utilities	33,038,000	37,941,000	15
Railroads	155,000,000	166,000,000	7
Exports	24,000,000	24,000,000	0
Beehive coke	52,450,000	52,450,000	0
Bunker—Foreign	7,700,000	10,000,000	30
Bunker — Domestic including Great Lakes	5,000,000	5,000,000	0
Used at coal mines for steam and heat	11,000,000	12,500,000	14
Total	560,010,000	625,593,000	12
Used from storage	4,375,000	....	
Exports	907,000	....	
Estimated production	554,728,000	....	
Substitution of coal for oil, mainly in west	....	2,000,000	
To increase stocks of industrial plants and public utilities outside of New England by ten days' supply	....	7,000,000	
Total requirements for 1918 without allowance for estimated conservation		634,594,000	
Production, 1917	554,728,000	....	
Production, 1918, required for needs	634,594,000	....	
Increase required	79,866,000		
Percentage	14.4		

Thirty-second Convention A.O.S.E.

The American Order of Steam Engineers held its thirty-second annual convention at Philadelphia, June 10-12, with headquarters at the Hotel Vendig. The several sessions were held at the Parkway Building, on Broad Street. The attendance was not as large as usual, owing to war conditions; there were fifty delegates present. The business of the convention was conducted with harmony and dispatch. The treasurer's report showed that the organization is in a sound financial condition. The Supplymen's Association held its exhibit in a large hall adjoining the meeting room of the delegates. There were 46 firms represented. This year a small table display took the place of the customary elaborate exhibit. The entertainment features were a smoker in the Parkway Building on Monday evening and an entertainment and dance at Moose Hall on Tuesday night. The following supreme officers were elected: J. William Pairent, chief; Eugene Enderle, first assistant chief; Harry Dunn, recording engineer; William S. Wetzler, corresponding engineer; William H. Tyson, treasurer; James G. Steigerwalt, senior master mechanic; C. F. Eisele, junior master mechanic; Harvey Berger, inside sentinel; John Orean, outside sentinel; James Lightfoot, chaplain; James K. Holland, trustee. The executive committee consists of George W. Richardson, Clifford P. Williams, and Franklin R. Moore.

At the meeting of the Supplymen on Tuesday the following officers were elected: Horace A. Smith, president; Porter G. Jones, vice president; Roy C. Downs, secretary; John W. Armour, treasurer; William Lindenfelser, Jr., director of exhibits. The date and place of the next meeting will be decided later by the supreme chief.

Coal Trade of Southern Chile

Consul John R. Bradley says, in *Commerce Reports*, that at this time there are no stocks of imported coal in Magallanes. For domestic consumption a lignite to the amount of about 3500 tons per month is produced locally, an analysis of which (perhaps a picked sample) is: Moisture, 18.752 per cent.; volatile matter, 37.892 per cent.; fixed carbon, 31.5 per cent.; and ash, 11.785 per cent. I am told, however, that the ash content is nearer 25 than 11 per cent. This coal retails now at the equivalent of $10 per ton, United States currency.

Prior to the war (and occasionally since its outbreak) practically all steam coal used here came from Cardiff and sold around $12 per ton. Most of that used here is now secured at Coronel, Chile, and is said to be a fair grade of bituminous. The yearly consumption of steam coal at Punta Arenas is estimated to be 15,000 tons, used by about twenty small steamers in the coasting trade, with this as their home port, and one freezing works, which uses about 2000 tons per annum. The other freezing works in this district burn wood, as does the electric-light plant, which pays about $10 per cord. Many of these plants would use coal if available at a reasonable price.

There are no facilities at Punta Arenas for handling coal, and it is unloaded by means of canvas slings and steam winches. Five or six hundred tons a day is about the usual progress made in unloading.

Coal Production Highest This Year

Bituminous-coal production for the week ended May 18 was estimated at 11,732,000 net tons, compared with 11,825,000 for the week ended May 11. The daily average for the week was 1,955,000 tons, compared with 1,971,000 tons for the week preceding, according to the reports issued by the United States Geological Survey.

Anthracite shipments were reported as 41,011 cars during the week of May 18, an increase over the previous week of 2244 cars, or 6 per cent.

The reports made by the United States Fuel Administration showing the working condition at the mines during the week of May 11 are especially interesting in that they reflect the operations of the mines for the weekly period showing the highest production since the organization of the Fuel Administration. The total losses from all causes during the week is recorded at 22.4 per cent. The losses were reported as follows: Car shortage, 11.2; labor shortage and strikes, 5.4; mine disability, 3.6; no market, 1; all other causes, 2.2. The percentage of production to total capacity for week ending May 11 was 76.6 per cent., the highest point attained this year.

Good Suggestion for Home Use Also

Every man that we send to France, whether for the firing line or behind it, will have to be supplied with electric service. The shops for repairing our rifles and guns in France will probably be larger than our munitions plants in this country, according to the *Electrical World*. As France has no coal to spare, we must either make use of some of our ships for transporting our own fuel to produce this power or obtain the power from other sources. The American way is pointed out. Hydro-electric power will not only provide for our own needs in France better than it can be done by sending over American coal, but the very large power needs of France herself can be met by American electrical plants.

Present development of hydro-electricity in France consists chiefly of small generating stations on streams, distributing current to a few near-by towns and villages. With American practice, it would be possible to develop all the available water power on a range of mountains and distribute it through several provinces. The sum of money required to build two 5000-ton steel colliers would build a 10,000 hp. hydro-electric plant in France, according to the estimates. Two such ships could easily take over all material required for construction. A plant of that character would require fewer than half a dozen men for operation. American electrical apparatus is now so practical and diversified that some of it can be set up outdoors with little shelter, and units of 1000 to 10,000 hp. can be located according to water power available and energy needs by American emergency construction which would have them in place and deliver power in from six to nine months.

Fuel Administration Warns Against Unnecessary Lighting

United States Fuel Administrator Garfield has warned the public against prodigal and unnecessary use of electricity for outdoor advertising purposes and other display illumination. Statistics obtained by engineers of the Fuel Administration reduced to terms of coal show the necessity for the utmost fuel economy during the summer as well as the winter, requiring the strictest conservation of fuel-generated electricity. The Administration expects that there will be no extravagant or unnecessary use of electricity for display purposes. If there is, the so-called lightless night order will be suspended and even more stringent restrictions will be ordered against all forms of outdoor lighting and display illumination. The consumption figures just compiled reveal the necessity for the utmost economy in fuel consumption during the summer as well as the winter and require the earliest enforcement of the strictest economy in all fuel-generated electricity.

Ancient Aeronautics

When floods washed away two bridges over the Nisqually River, the Standard Oil Co. of California had to revert to primitive methods to get oil supplies to the eastern half of Lewis County. A large cable was strung across the river, and for three weeks this aërial ferry was the only line of communication. An automobile was used to furnish power at one end, while strong men operated the device from the other. Oil was sent over in 5-gal. cans, and from these filled into barrels. Factories and motorists of Lewis County were thereby permitted to continue using gasoline and other oil products uninterruptedly. — *The Wall Street Journal Straws.*

New Publications

THE STORAGE OF BITUMINOUS COAL. By H. H. Stock. Published by the University of Illinois, Engineering Experiment Station, Urbana, Ill. Paper, 6 x 9 in.; 192 pages. Price, 40c.

This book, which is a bulletin of the University of Illinois and designated as Circular No. 6, is perhaps the most comprehensive publication yet written on the subject of the storage of coal. There are 63 illustrations and 7 tables. It is the purpose of this circular to present a review of modern practice covering the storage of coal and a statement of the facts that have developed in the experience of those who have successfully or otherwise undertaken to store coal. The discussion is confined largely to bituminous coal, which has given so much trouble, owing to its tendency toward spontaneous combustion while stored, and to storage systems and mechanical devices.

MODERN LOCOMOTIVE VALVES AND VALVE GEARS. By Charles L. McShane. Published by Griffin & Winters, Chicago. Cloth, 317 pages; 5 x 7½ in.; 113 illustrations. Price, $2.50.

In writing this book the author has assumed that the reader has no previous knowledge of valves or valve gears, and so he begins with fundamentals. He describes the working of the plain slide valve with neither lap nor lead and then proceeds to show the effects produced by giving lap and lead to the valve and angular advance to the eccentric. From a study of the plain slide valve he passes naturally to special forms of slide valves, balanced valves and piston valves. A striking feature of the book is the omission of the valve diagrams so commonly used in books on valve gears for the solution of valve-motion problems. Instead, a simplified displacement diagram is employed to show the relative positions of valve and piston at admission, cutoff, etc. Apparently this diagram does not take into account the effect of connecting-rod angularity. The Walschaert, Baker-Pilliod, Southern and Young types of valve gear are taken up in detail and instructions are given for setting each and for making the necessary repairs in case of breakdown on the road. The language of the author is simple and direct, and the text is supplemented and explained by a large number of excellent illustrations. A commendable feature is that the various diagrams are pertinent to the discussion and no illustrations are used merely for the purpose of adding to the length and appearance of the book. A full list of definitions of terms forms part of the work, which is thoroughly practical throughout and should be of value to apprentice, fireman, engineer and mechanic.

ELEMENTS OF MACHINE DESIGN. By Henry L. Machman. Published by John Wiley & Sons, Inc. New York. Cloth, 245 pages; 5¾ x 9 in.; illustrated. Price, $2 net.

The contents of this volume are arranged under three headings, the first relating to the strength of material, the second to fastenings, which include screw fastenings, riveted joints, keys and cotters, and shrink-and-force fits. The third section is devoted to transmission machine parts. This includes the chapters on shafts and axles, couplings and clutches, journals and bearings, belts and pulleys, friction wheels, tooth gears, rope transmission, chain gearing, pipes and cylinders, valves, flywheels, crankshafts, crankpins, and eccentrics, connecting-rods, piston rods and eccentric rods, pistons, crossheads and stuffing-boxes, hoisting-machinery data and springs. There are 22 chapters in all, the last one being devoted to the materials of machinery.

This book is intended primarily as a classroom textbook and is of more use to the student on the whole than it is to the operating engineer, although the latter will find much of value if he is interested in figuring out or designing machine parts. The author has developed the equations for the design of the more common machine elements, which have been done concisely, and frequently only an outline of the deduction has been given. Empirical formulas and rule-of-thumb methods have been avoided as far as possible.

Illustrations have been chosen to show typical construction rather than a great variety. Each subject treated is designated by black-face type, which makes it convenient to the reader when looking for any particular subject.

MECHANICAL LABORATORY METHODS OF TESTING MACHINES AND INSTRUMENTS. Second Edition. By Julian C. Smallwood. Published by D. Van Nostrand Co., New York. Leather, 399 pages; 5 x 7¼ in.; 114 illustrations. Price, $3.

This second edition has been revised and enlarged to a considerable extent. As the title of the book implies, it is devoted to methods employed in testing various apparatus found in power plants as well as for laboratory uses. In dealing with the various classes of instruments this volume briefly explains the principle of design and operation. The illustrations used to assist in such explanations are diagrammatic so as to make a simple presentation. Such instructions as to how to operate engines, boilers, etc., have been omitted, as the reader is supposed to know about such matters.

In enlarging this volume, the section dealing with instruments contains a number of subjects not covered in the previous edition, and this especially applies to recorders. Furthermore, the section treating on valve setting and steam-engine testing has been enlarged and improved. Engineers will be interested in the section devoted to the testing of condensers and feed-water heaters and other auxiliaries; also in the new section that has been added on the testing of refrigerating machinery, ammonia, absorption and compression systems. Another added feature relates to the testing for the horsepower output of electric motors which should be convenient in connection with the testing of motor-driven units. In all there are twelve additional tests.

Owing to the manner in which the text matter has been got together, the volume is not above the head of the average engineer, and although there are numerous formulas, none are of such character as to prevent one with a common knowledge of mathematics from working them out. In fact, numerous problems have been worked out to assist in their comprehension.

MANUFACTURING OPPORTUNITIES IN THE STATE OF WASHINGTON

Issued by the Department of State through its Bureau of Statistics and Immigration, setting forth the manufacturing opportunities in that state. The book has 240 pages, 5½ x 8½ in., 75 illustrations and several maps. It is the result, as set forth in the preface, of a more or less complete survey of conditions favoring the establishment of additional manufacturing plants in the state, but the broadness and diversity of the subjects discussed preclude the presentation of details. Additional information and any possible assistance will be gladly furnished by the State Bureau of Statistics and Immigration, the Industrial Bureau of the State University, and the Departments of Science and Engineering of the State University and State College.

Personals

F. F. Espenschied, who has been assistant engineer with the Hydro-Electric Power Commission of Ontario, Canada, and prior to that was general manager of the Interstate Light and Power Co., Galena, Ill., has joined the forces of the Combustion Engineering Corporation, 11 Broadway, New York City.

Engineering Affairs

The Society of Automotive Engineers will hold a meeting at Dayton, Ohio, June 17-18. The papers will treat on refining of petroleum, aëronautic engineering, tractor engineering and the design of heavy fuel engines.

Miscellaneous News

A Boiler Exploded in an automobile and bicycle rim factory at Onaway, Mich., on May 30, killing one person.

A Boiler Exploded on a mine engine used at Jackson mine, Lonaconing, Md., on June 1, injuring an engineer and a miner who were riding to the mine.

A Boiler Explosion in the plant of the Monogram Laundry Co., at Muskegon, Mich., on May 30, practically wrecked the building. Although the explosion occurred during working hours, nobody was injured.

A Flywheel Exploded in the electric light and water plant of Clay Center, Kan., on May 26, killing the chief engineer and completely wrecking the electrical and water-works plants, causing a damage estimated at nearly $40,000. Parts of the flywheel were found one block from the plant. The engine was a Skinner Unaflow, and a defective governor is thought to have caused the trouble.

Two Boilers Exploded at the Hammer Lumber Co.'s mill, 25 miles east of Conway, S. C., on May 27, killing five men and injuring five others. The explosion is the worst recorded in the county, and the cause is given as being high steam pressure. The boilers were hurled 300 yards, one piece being thrown nearly a mile. Beside the loss of life considerable damage was wrought upon the plant.

A Boiler Explosion in the plant of the Bartlett Lumber Co., at Shelldrake, in an isolated part of Chippewa County, Michigan, on June 3, is reported as having caused the deaths of ten men and injuries to a number of others. As there is no direct wire communication with the settlement and to reach it involves a boat trip of nearly 50 miles, the authorities, at this writing, were having difficulty in obtaining definite information concerning the cause of the explosion.

The Chicago Wireless Institute, the object of which is to prepare men to pass the United States Government examination necessary to obtain a first-grade radio operator's license, is at 220 South State St., 800 Consumers Building. Day classes are held five days a week from 1 to 5 o'clock, and evening classes from 7 to 10 o'clock. The instructing engineer is R. R. Haugh, of Detroit, who is a member of the American Institute of Radio Engineers. The tuition fee is $50 for the entire course.

The College of the City of New York is giving a special course in shipbuilding and navigation under the direction of John Martin, formerly nautical expert, Hydrographic Office, U. S. N., which began Tuesday, June 18 and will close Sept. 14. In this intensive course the instructor will attempt to prepare students who have had the necessary fundamentals of the service, mathematics and elementary mechanical drawing, for positions of tracers and draftsmen in Government shipyards. These workers are much needed, and the pay varies from $25 to $40 per week. Those desiring to take this course should communicate with the college, Room 16, Main Building, 139th St. and Convent Ave., New York City.

Trade Catalogs

"Centrifugal Boiler-Feed Pumps." The De Laval Steam Turbine Co., Trenton, N. J. Bulletin N; 8½ x 11 in. Describes the De Laval combined steam turbine and centrifugal boiler-feed pump, and also electric motor-driven units.

The Wheeler Condenser and Engineering Co., Cartaret, N. J., has, under agreement with the Sugar Apparatus Manufacturing Co., acquired the exclusive right to manufacture and sell evaporating apparatus under the patents of S. Morris Lillie, president of that company.

The Lillie Evaporator. The first booklet relating to the Lillie Evaporator, published by the Wheeler Condenser and Engineering Co., Carteret, N. J., is just off the press. The device is now manufactured exclusively by this company under agreement with the Sugar Apparatus Manufacturing Co., owners of the Lillie patents. This new booklet calls attention to the factors which make the evaporator especially suited to the concentration of waste waters or liquors in numerous industries. Five pages are devoted to tables that are of especial value in the evaporation industry. A folding page insert gives instructions for operating Lillie quadruple effects.

Scientific Industrial Illumination is the title of a 36-page illustrated booklet recently issued by the Holophane Glass Co., 340 Madison Ave., New York City. It is divided into four parts. The first part shows the need for scientific illumination and discusses its economic advantage. The second discusses the fundamental principle of scientific illumination. The third describes and illustrates new types of industrial lighting units manufactured by the company for shop, factory, office and drafting room illumination and for yard and protective lighting. The fourth contains a collection of general engineering data which should make this booklet valuable for ready reference.

NEW CONSTRUCTION

Proposed Work

Mass., Lawrence—The United States Worsted Co. plans to build a steel boiler house. Estimated cost, $25,000.

Conn., New Britain—The State Board of Education, Capitol, Hartford, will receive bids until June 18, for the installation of a modulation and heating system in the State Normal School on Prospect St. Davis & Brooks, Lewis & Gold Sts., Hartford, Arch.

N. Y., Amsterdam—J. Kayser and Co., 34 Elk St., plans to build an addition to its power plant in connection with its proposed 4 story, 100 x 200 ft. silk mill. W. Higginson, 13 Park Row, New York City, Arch.

N. Y., Central Islip—The State Hospital Commission, Capitol, Albany, received an only bid for installation of a heating system in the Central Islip State Hospital, here, from the W. B. Armstrong Co., 3 Fulton St., Albany, $36,588 and for the lighting system, from the Babcock and Wilcox Co., 85 Liberty St., New York City, $66,933.

N. Y., Newark—A. W. Beaven, Pres. of the Board of Managers, New York State Custodial Asylum for Feeble Minded Women, Newark, will receive bids until June 28, for the installation of a heating plant and equipment for same. Noted Apr. 30.

N. Y., Brooklyn—The Lasky Motor Car Co., 17 Grahm Ave., is in the market for electric motors, etc., to be installed in its garage.

N. Y., Long Island City—L. Gold, 44 Court St., Brooklyn, will install a steam heating plant in its proposed 2 story, 95 x 100 ft. garage to be erected on Webster and 5th Ave. Total cost, $75,000.

N. Y., Long Island City—The Racich Asbestos Co., 609 West 55th St., New York City, plans to install a steam heating and steam piping system, boilers, 3 electric motors, etc., in its proposed 3 story factory on Hancock St. and Harris Ave. Total cost, $60,000. E. Richardson, 100 Amity St., Arch.

N. Y., Warwick—The Board of Inebriety, 300 Mulberry St., New York City, plans to build an Institution group. Various units include dormitories, power house, etc. Total cost, $200,000. S. Levy, Pres. C. B. Meyers, 1 Union Sq., New York City, Arch.

N. J., Jersey City—R. W. Sailer, Arch., 76 Montgomery St., is receiving bids for the installation of electric lighting, heating and power systems in the proposed 4 story factory on Montgomery St., for the National Grocery Co., Montgomery St.

Md., Baltimore—The Mallory Machinery Co., 522-524 Light St., is in the market for a 150 K. W. or 200 kw. d.c. direct-connected generating set; 250 volt with field rheostat.

W. Va., Kingwood—The Hoffman Coal Mining Co., recently incorporated with $30,000 capital stock, plans to build an electric power plant in connection with its mine. O. Hoffman, Pres.

N. C., Hiawasse—The Carolina Tennessee Power Co., c/o Bertrom Griscom & Co., 421 Chesnut St., Philadelphia, Penn., has received court's permission to erect a hydro-electric plant on Hiawasee River. The project involves developing 60,000 hp. for transmission by electricity.

La., Rayne—City issued $35,000 bonds to improve the electric-light plant and water-works.

Ohio, Lorain—The W. S. Automatic Co. plans to build a 40 x 120 ft. power plant in connection with its proposed new factory. Total cost, $100,000.

Ill., Chicago—The Board of Local Improvement is in the market for electrical power equipment in connection with its proposed Michigan Ave. improvement project. Total cost, $2,000,000. C. O. Hill, Engr.

Ill., Chicago—The Bunting Boiler Co., Lowell Ave., is having plans prepared for the erection of a 1 story, 75 x 200 ft. boiler plant on 16th St. Estimated cost, $30,000.

Ill., Woodstock—The Woodstock Typewriter Co., North Dearborn St., Chicago, plans to build a 1 story, power house here. Estimated cost, $10,000.

Wis., Milwaukee—A. C. Downing, 787 Shepard Ave., is in the market for boilers, engines, generators, motors, etc., in connection with its proposed 225 x 250 ft. plant. Total cost, $150,000. O. C. Uehling, 511 First National Bank Bldg., Engr.

Colo., Loveland—City issued $79,000 bonds for the erection of an electric lighting plant.

Wash., Vancouver—The Columbia River Interstate Bridge Commission, Clarke Co., will receive bids until June 28, for the erection of a transformer house on Washington St.

Man., Gladstone—City plans to build an electric lighting plant soon. About $15,000 is available for the project.

CONTRACTS AWARDED

Mass., Boston—The Bureau of Yards & Docks, Navy Dept., Wash., D. C., has awarded the contract for improvements to its power plant at the Navy Yard, here, to Rideout Chandler and Joyce, 178 High St. Estimated cost, $31,000. Noted June 11.

Mass., Boston—The United States Government has awarded the contract for the installation of electricity in the Boston Quartermasters Terminals, South Boston, to E C. Lewis ,Inc., 21 Federal St. Estimated cost between $1,000,000 and $1,500,000.

N. Y., Buffalo—The Buffalo General Electric Co., 206 Electric Bldg., has awarded the contract for the erection of a 1 story, 100 x 110 ft. power sub station, on State St., to Huntley & Derdinger, Electric Bldg. Estimated cost, $25,000. Noted June 11.

N. Y., Buffalo—Cousins & Co., 74 Wabash St., has awarded the contract for the erection of a 1 story, 95 x 125 ft. boiler shop, to B. I. Crocker, 57 Builders Exchange. Estimated cost, $35,000. Noted May 28.

N. Y., Mineola—The Curtiss Aeroplane Co., 1927 Elmwood St., Buffalo, has awarded the contract for the erection of a 1 story, 100 x 260 ft. factory, to the J. W. Cowper Co., Fidelity Bldg., Buffalo. Estimated cost, $35,000. Electric traveling cranes will be installed in same.

N. J., Newark—The Board of Education will soon award the contract for the installation of heating, ventilating and electric systems in all public schools in the city.

N. J., South Amboy—The Board of Education has awarded the contract for the installation of a heating system in its proposed 3 story, 90 x 150 ft. school on John St., to the Johnston Heating Co., 131 East 26th St., New York City. Estimated cost, $10,500.

Ohio, Caledonia—City has awarded the contract for the construction of an electric transmission line from here to Marion, to Kelly & Pommert, Caledonia.

Ohio, Cleveland—The Board of Education has awarded the contract for the erection of a 3 story, brick and concrete shop, boiler and coal room addition to the school at 2486 East 46th St., to H. F. Juergens Co., East 49th St. and Gladstone Ave. Estimated cost, $79,300.

Ohio, Cleveland—The Steel Products Co., 2196 Clarkwood Ave., has awarded the contract for the erection of a 1 story, 45 x 70 ft. power house at 2188 East 65th St., to S. W. Emerson, 1900 Euclid Ave. Estimated cost, $17,000.

Wis., De Pere—The De Pere Manufacturing Co. has awarded the contract for the erection of a 100 x 100 ft. brick boiler shop, to A. J. Beauregard, De Pere. Estimated cost, $15,000. Equipment will be installed by the owner. Noted June 4.

Wis., Kenosha—The Simmons Manufacturing Co., Pearl St., has awarded the contract for the installation of a heating system in the proposed office building, to the Downey Heating and Supply Co., 613-5 Clybourn, Milwaukee.

Iowa, Clinton—The Climax Engineering Co., c/o C. B. Stebbins, foot of 4th St., has awarded the contract for the erection of a 1 story, 50 x 90 ft. power house, to Haring Bros., 402 Wilson Bldg.

Iowa, Fonda—The Fairburn State Bank has awarded the contract for alterations to a 2 story, 25 x 80 ft. bank, to A. Moorman & Co., 501 Minneapolis St., St. Paul, Minn. A low pressure steam heating plant will be installed in same.

Iowa, Pomeroy—The First National Bank has awarded the contract for the erection of a 1 story, 27 x 50 ft. bank building, to A. Moorman & Co., 501 Minneapolis St., St. Paul, Minn. A low pressure steam heating plant will be installed in same.

Mo., Carthage—The Board of Education will soon award the contract for the installation of ventilating plants in two ward schools. Plans include engines, motors, fans and heating coils. Estimated cost, $10,000. J. H. Felt & Co., 802 Grand Ave., Temple, Kansas City, Mo., Arch.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular Current	Individual Current
Buckwheat	$4.60	$7.10—7.35
Rice	4.10	6.65—6.90
Boiler	3.90	....
Barley	3.60	6.15—6.40

BITUMINOUS

Bituminous not on market.

Pocohontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.00 a year ago.

*All-rail to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* are as follows:

ANTHRACITE

	Circular Current	Individual Current
Pea	$4.90	$5.65
Buckwheat	4.45@5.15	4.80@5.50
Barley	3.40@3.65	3.80@4.50
Rice	3.90@4.10	3.00@4.00
Boiler	3.65@3.90	....

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Gross	Mine Price Net	Gross
Central Pennsylvania..	$5.06	$3.05	$3.41
Maryland—			
Mine-run	4.84	2.85	3.19
Prepared	5.06	5.05	3.41
Screenings	4.50	2.55	2.85

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty, Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The ratte to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Current	One Yr. Ago	Current	One Yr. Ago
Pea	$3.45	$3.10	$4.35	$4.00
Barley	2.15	1.90	2.40	2.15
Buckwheat ..	3.15	2.90	3.75	3.80
Rice	2.65	2.40	2.65	3.40
Boiler	2.45	2.20	3.55	3.30

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes..	$2.55—2.70	$3.25—3.40
Mine-run	2.35—2.50	3.00—3.15
Screenings	2.05—2.20	2.75—2.90

St. Louis—Prices per net ton f.o.b. mines are as follows:

	Williamson and Franklin Counties	Mt. Olive & Staunton	Standard
6-in. lump ...	$2.55-2.90	$2.55-2.70	$2.55-2.70
2-in. lump ...	2.55-2.90	2.55-2.70	2.55-2.70
Steam egg ...	....-....	....-....	2.20-2.40
Mine-run	....-....	2.35-2.50	2.00-2.20
No. 1 nut....	2.55-2.90	2.55-2.70	....-....
2-in. screen ..	2.05-2.20	2.05-2.20	....-....
No. 5 washed.	2.05-2.20	2.05-2.20	....-....

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump & Nut	Slack and Screenings
Big Seam	$2.05	$2.35	$1.75
Pratt, Jagger	2.25	2.55	1.95
Corona	2.30	2.65	1.95
Black Creek, Cahaba.	2.75	3.00	2.35

Government figures.

Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

THEY CALL THEM DEVIL-HOUNDS
BUT THEY ARE SIMPLY
HOUNDING
THE DEVIL
OUR MARINES

POWER

Vol. 47 NEW YORK, JUNE 25, 1918 No. 26

THE WAR'S BENEDICTION

FATE sits on the rim of Heaven writing a New Genesis. Here a line with the blood of heroic dead, there a line with the tears of sorrowing women.

The words are the nebula of Human Aspirations. And the composition assumes form by force of the gravity that is Brotherhood.

We shall read it by the light of a sun that is the New Purpose, for the past is Ptolemaic and the future Copernican.

In this Apocalypse there are no chosen people. The rich, the poor, the toiler and the master alike are led from the bondage of the Past's insecurity.

The pathway is bloody and appalling. Yet from it rises a mighty hallelujah of Deliverance.

FEAR NOT,
ye Kings of Capital!
STRIKE NOT,
ye Toiling Millions!
BE PATIENT,
ye Engineers!

YE are the New Trinity that is come with one mind, one heart, one purpose—to conduct as one unit this machine called Civilization; not for wealth or vain aggrandizement, but to make the world a better place to live in. And in the living and the service find the true reward.

By CHARLES H. BROMLEY

Operation and Maintenance of Elevators—Geared Traction Machines

BY R. H. WHITEHEAD

The construction and operation of the geared type of traction-elevator machines are discussed. Three types are considered: The overhead machine using a secondary-idler sheave; basement type using a secondary idler sheave; and overhead type without a secondary idler sheave, but employing a traction driving sheave having V-shaped grooves.

WITH the winding-drum type of elevator machine, the limitation of car rise is determined by the drum dimensions and these fix the car travel to about 150 ft. To meet the elevator problems evolving as the result of modern skyscraper buildings, another type of elevator machine had to be developed. This is known as the traction type and derives its name from the fact that instead of the ropes being wound upon a drum to give the car motion, as in the winding-drum type, motion is obtained by means of the traction existing between the driving sheave and the hoisting ropes.

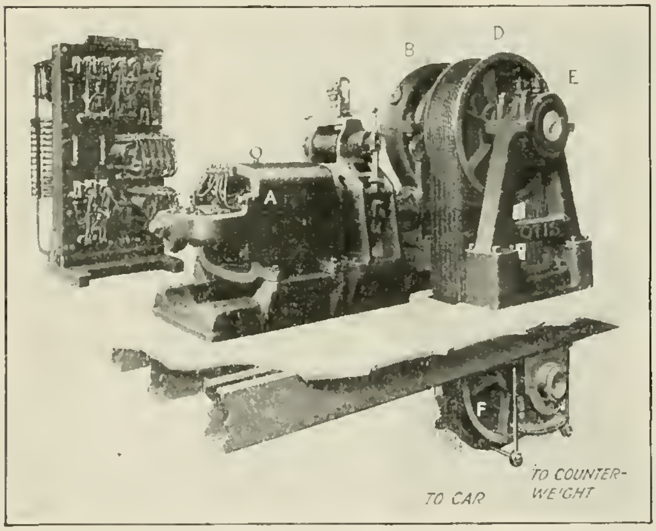

FIG. 1. GEARED TRACTION ELEVATOR MACHINE

There are two general types of traction machines—geared, Fig. 1, and gearless, Fig. 2. The geared type is used for low and medium rises and car speeds up to about 350 ft. per min., while the gearless type is used for high lifts and car speeds up to 600 and 700 ft. per min. Two of the gearless-traction elevator machines in the Woolworth Building, New York City, have an actual car travel of 680 ft. Geared-traction machines are also frequently used for low lifts in place of the drum type of machine.

It will be seen from Fig. 1 that the geared type of traction machines is similar in appearance to the winding-drum type, having a motor *A*, worm and worm gear in the case *B*, and a brake wheel and brake *C* mounted between the gear and motor. However, instead of the spirally grooved drum used on the winding-drum machine, a multi-grooved driving sheave *D* is keyed to what is the drumshaft in the drum-type machine. The grooving on a drum-type machine forms a helix starting from one end of the drum and running to the other end or ending at the center, as the case may be. On the traction machine the grooves on the sheaves form closed circles about the sheave, the number of grooves depending upon the number of ropes, generally two grooves for each rope.

In passing, attention might be called to the arrangement of the gearless type of machine, Fig. 2. It will be seen that, as the name would indicate, no gears are used, the driving sheave being mounted directly on the motor shaft, along with the brake wheel. This means that a very slow-speed motor must be used. This type of machine will be given further consideration in another article.

The geared-type traction-elevator machine, as shown in Fig. 1, is the equivalent for load and speed to the drum-type machine, using the same motor, brake and gears, the main difference being, as previously mentioned, that the geared-traction machine uses a driving sheave instead of a spirally grooved drum of the same diameter. The general type of traction machine employs the use of a grooved secondary idler sheave *F*, as shown in Fig. 1, to obtain sufficient tractive effort.

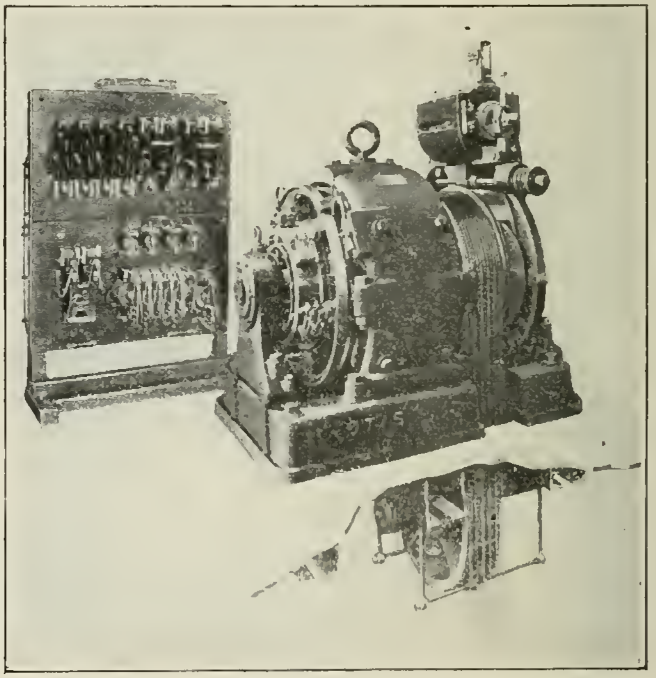

FIG. 2. GEARLESS TRACTION ELEVATOR MACHINE

In the traction type of installation the ropes are continued from the car to the counterweights, just as the car-counterweight ropes are in the drum type, but in the former only one set of counterweights is used. The roping for an overhead machine of the general type is shown in Figs. 3 and 4. The ropes pass

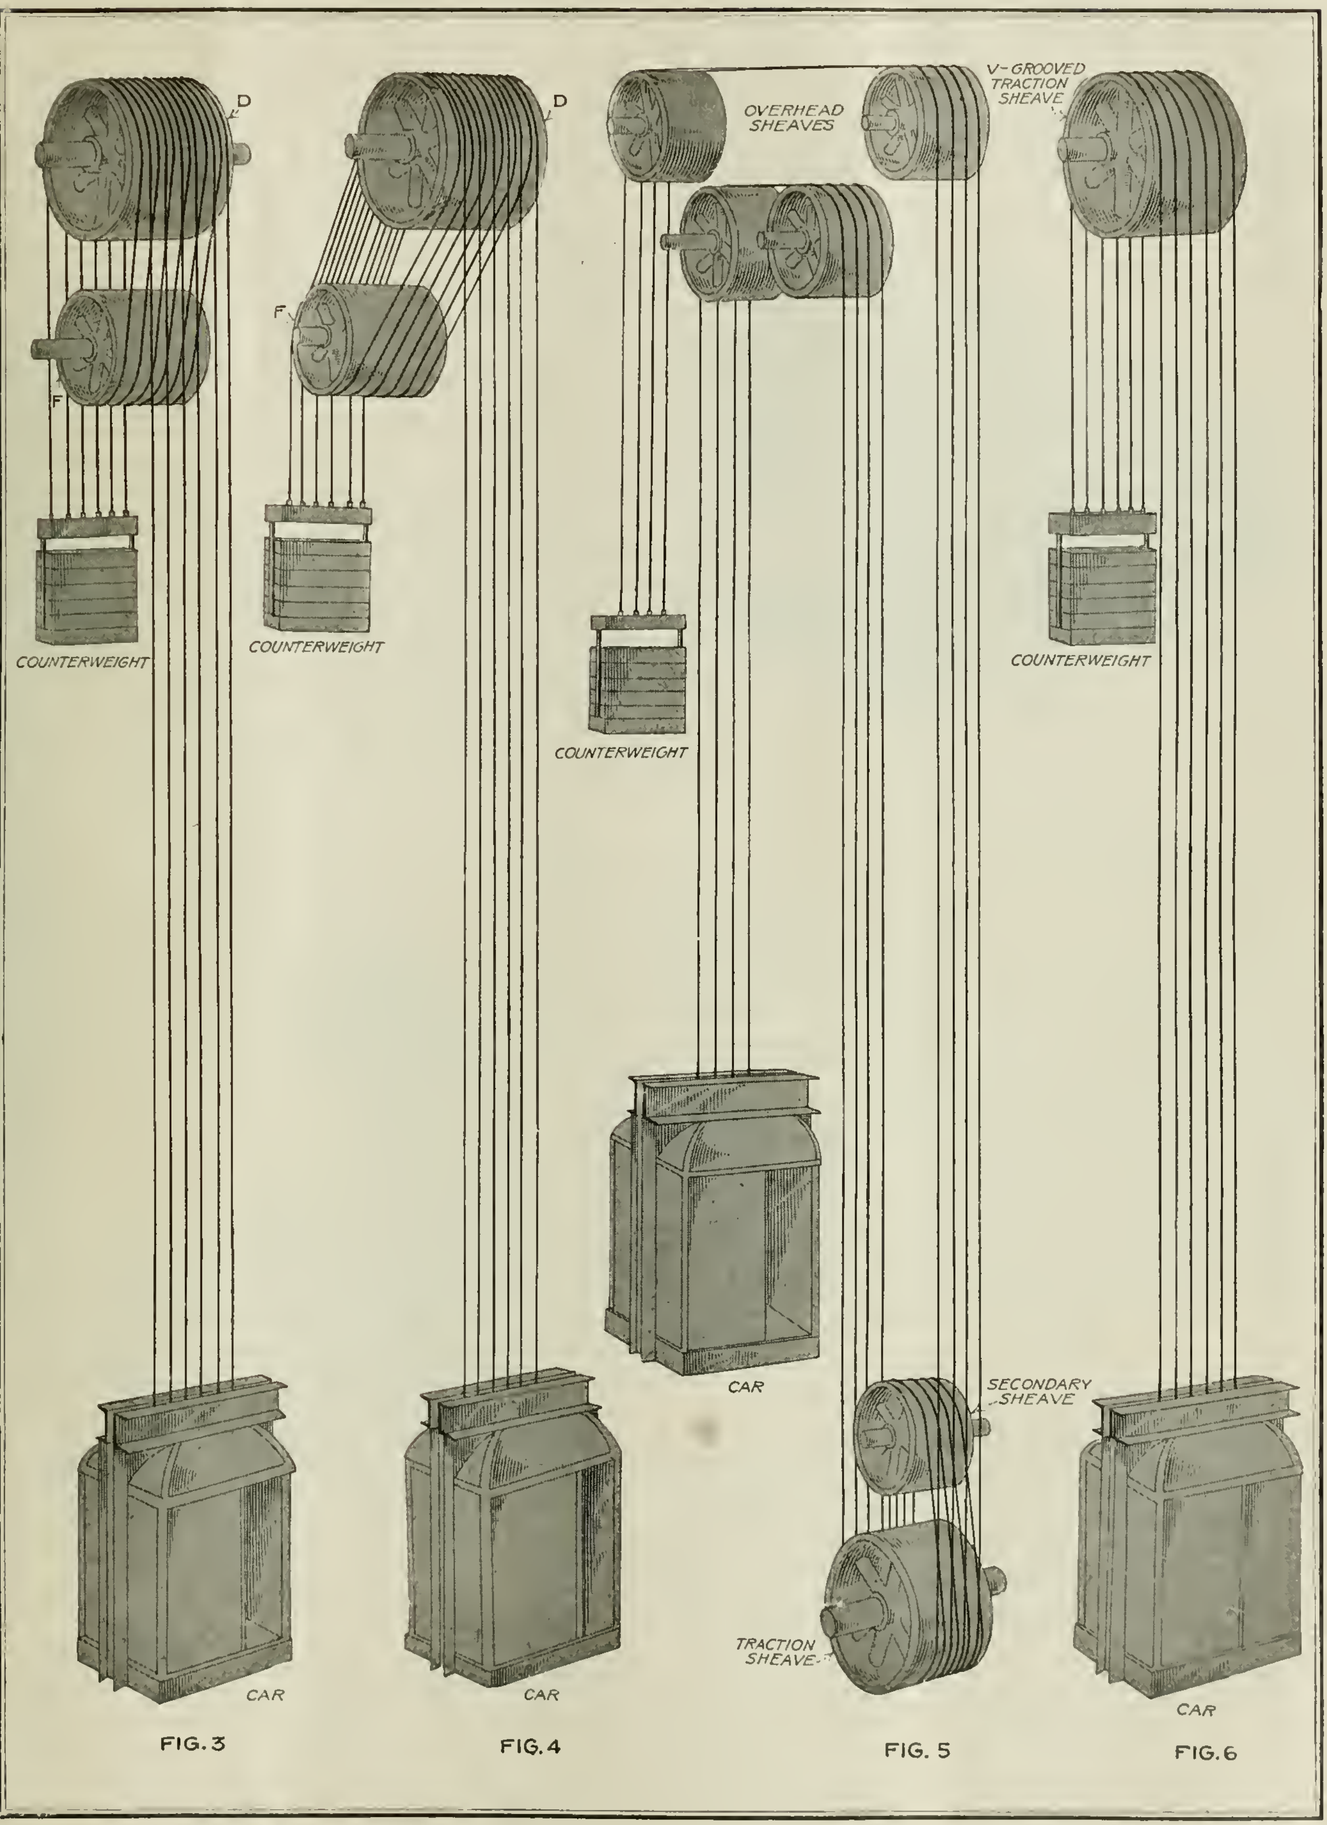

FIG. 3 FIG. 4 FIG. 5 FIG. 6

FIGS. 3 TO 6. DIFFERENT ARRANGEMENTS OF ROPING UP TRACTION ELEVATOR

Figs. 3 and 4—Cable arrangement when machine is located overhead. Fig. 5—Roping scheme when machine is located in the basement. Fig. 6—Roping up when a V-grooved traction sheave is used.

from the car over separate grooves in the driving sheave *D* down and around under the idler sheave *F*, up over the traction sheave *D* again and then down to the counterweights. It is seen from this that the car is connected to one end of the cables and the counterweights to the other. This scheme of roping up the car and counterweights gives sufficient friction between the sheave and rope to get the proper tractive effort for all conditions of load.

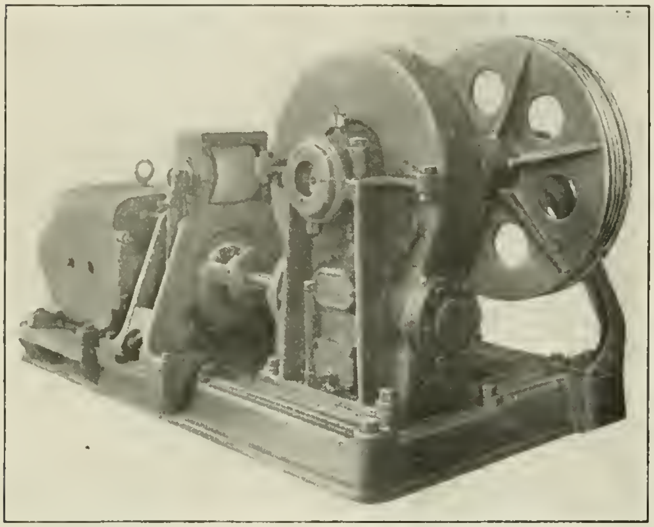

FIG. 7. V-GROOVED DRIVING-SHEAVE TYPE TRACTION ELEVATOR MACHINE

In Figs. 3 and 4 there are six cables. To accommodate them on the sheaves there must be twelve grooves in the sheaves. These six cables as they come from the car fall into every other groove on the driving sheave; that is, starting from one end of the sheave, say in grooves 1, 3, 5, 7, 9 and 11, they pass down around in grooves of the same number in the secondary sheave and up into the remaining grooves in the driving sheave. This would bring rope No. 1 into grooves 1 and 2 of the driving sheave and in groove No. 1 in the secondary sheave, leaving groove No. 2 in the secondary sheave unoccupied when this sheave is located directly under the driving sheave, as in Fig. 3.

Where the driving sheave spans the distance between the center of the car and counterweights, as in Fig. 3, the use of the secondary sheave permits of having slightly more than two complete half-turns of contact with each rope on the driving sheave. This is on account of the idler sheave being somewhat smaller in diameter than the driving sheave. When the driving sheave does not span the car and counterweight centers, as in Fig. 4, the secondary sheave is also used as a deflector sheave, but doing this results in losing a small amount of rope contact on the driving sheave, consequently some traction. From Fig. 4 it will be seen that the same number of grooves are occupied on the secondary sheave as on the traction sheave.

Experiments made with well-lubricated ropes and also with dry ropes on traction sheaves of this type show that with an installation properly designed there is no slippage of rope on the driving sheave under any condition of loading excepting a slight slippage which sometimes occurs when the car is suddenly stopped or started.

In some cases a V-shaped groove is used instead of the regular semicircular rope-shaped groove on the driving sheave. This groove is shaped like the letter V as implied by the name, and the traction is obtained on the driving sheave without the use of a secondary sheave, from the wedging action between the grooving and the ropes. A geared traction machine of this type is shown in Fig. 7. This is similar to the winding-drum type in every detail, except in place of the drum a sheave having a number of V-shaped grooves in its periphery is used, as shown in the figure. The ropes run directly from the car over the driving sheave down to the counterweights, as shown in Fig. 6.

The V-grooved machine costs less to build than the semicircular-grooved type, Figs. 1 and 2, since not only is the secondary sheave omitted, but in addition it is possible to use lighter construction on the driving sheave and shaft as the downward strain is only one-half as much. The driving sheave is only one-half as wide, as the ropes are not doubled back as in the case of the type using a secondary sheave.

The V-grooved type, however, gradually loses its tractive effort due to the wearing of the groove by the rope. This wear tends to make the grooving semicircular and when this occurs, the ropes will start to slip, as they no longer wedge in the groove. With the secondary-sheave type the tractive effort does not decrease with increased usage, since the grooves remain the same shape and the rope contact therein remains the same.

The traction type of elevator machine should always be installed overhead if possible, as shown in Figs. 1 and 2. The basement type of geared-traction machine is shown in Fig. 8. The roping of such a machine is given in Fig. 5. A comparison of Fig. 5 with Figs. 3 and 4, for an overhead installation, shows that for the same rise about twice the amount of rope is required for the basement-type installation, and in addition the rope must be deflected over several extra sheaves. This results in shorter rope life and higher

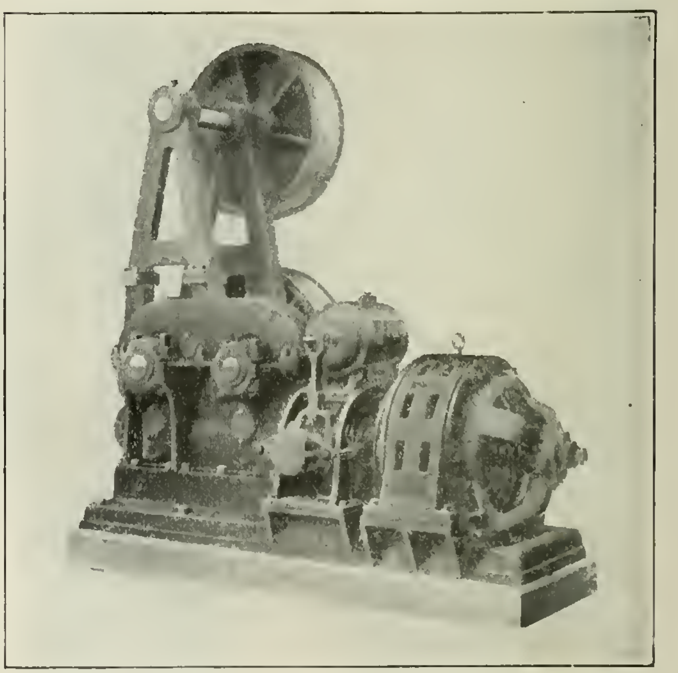

FIG. 8. BASEMENT TYPE OF TRACTION ELEVATOR MACHINE

power consumption, and the first cost of the installation is greater, not only on this account but also for the extra overhead sheave.

In Figs. 1 to 4 it will be noticed that there are six independent ropes leading up from the car to the driving sheave, then to the secondary sheave and back to the driving sheave and to the counterweights. These ropes are usually steel and are $\frac{5}{8}$ in. to $\frac{3}{4}$ in. in diameter. With this type of installation it is important that the strain be kept equal in all ropes by adjusting them with the take-up arrangement provided on the car crosshead and counterweight frame. When any one of the ropes takes less than its share of the load, this particular rope loses its traction and a loss of traction results as a whole.

Each rope is provided with a swivel hitch of the ball-socket type. This prevents any twisting strain on the ropes and relieves them of the bending strain at the hitch. With the general type of traction machine using a secondary sheave, the minimum traction under any condition is such that the rope will not slip until the load on the heavy side is about twice that on the light side, which means that with the machine 40 per cent. over-counterweighted the load on the car must equal about 200 per cent. rated capacity before there is any danger of the cables slipping on the driving sheave.

Slippage a Point in Favor of This Type

The fact that slippage will occur is a very strong point in favor of this type of installation, because when the car bottoms in the pit the traction is lost and the counterweights cannot travel farther; even though the driving sheave continues to turn, it cannot exert sufficient tractive effort on the ropes to haul the counterweights into the overhead work. This also applies when the counterweights bottom in the pit; the driving sheave cannot pull the car up into the overhead work.

A machine automatic like that used on the drum machine for stopping the car at the top and bottom landing cannot be used on the geared-traction machine, because of a possible slippage of the cables under the conditions enumerated. Consequently, additional switches instead are provided, similar to the hoistway-limit switches, at the top and bottom of the hoistway. These switches are operated by the cam on the car that operates the hoistway-limit switches and fulfills the same function as the automatic located on the drum shaft of the winding-drum type of machine.

The first limit brings the car down to slow speed, in the case of a direct-current motor, by opening the circuit to the magnet coil, which weakens the shunt field, thereby increasing the field strength to normal value, and with an alternating-current motor slow-down is accomplished by disconnecting the high-speed winding of the motor from the line and in its place connecting the slow-speed winding. The next limit switch generally opens the direction switch for the direction of car travel, and farther travel of the car will open the hoistway-limit switch, which opens the main potential switch. High-speed installations, where the control is more complicated, will be discussed in a future article.

The limit switches, wherever conditions permit, should let the reversing switches open automatically when the car is level with the top and bottom landings, and a normal automatic stop with any load in the car should not operate the hoistway limits.

The rope length should be adjusted so that the counterweight does not bottom until after the top hoistway-limit switch opens. Conditions of overhead car and counterweight clearance sometimes necessitate deviation from the foregoing and make it necessary for the reversing switches to open automatically before the terminal landings are reached, the inertia of the machinery being depended upon to bring the car to the landing. This is objectionable inasmuch as the operator tends to stop the machine on the limits instead of the automatics, and if he uses the car switch and stops the car before the floor level is reached, he must go back and make another trial.

Geared-traction cars are sometimes provided with appliances used ordinarily on the gearless type; that is, stopping switches mounted on the car, operated by a cam in the hoistway, instead of the limit switches previously described; and oil buffers instead of spring buffers for both car and counterweight are used.

Ordinarily, however, the geared-traction installation is a duplicate of the winding-drum type except for the difference as shown in this article, and with this type of machine it is possible with either alternating or direct current to meet the elevator problems in high-rise installations for moderate speeds.

As pointed out in the foregoing, the geared-traction machine is generally used only for car speeds up to 350 ft. per min., and for speeds of 400 to 700 ft. per min. the gearless type is used.

As in the winding-drum type of machine, the driving-sheave shaft is equipped with marine collared bearings in the outboard stand and in the wormwheel case to resist the side thrust of the wormwheel. The geared-traction machine is also built either on the single-screw type, Fig. 1, or the double-screw type, Fig. 8. Thrust bearings are provided on the wormshaft of the single-screw machine to take the thrust between the worm and gear. In the double-screw type no thrust bearings for the wormshaft are required as a right and a left worm on the same shaft engages a right and a left wormwheel, which in turn mesh as spiral gears, thus forming a three-point drive.

Pollution of Streams

"The court knows judicially that modern science has demonstrated that the use of water in power plants and for other purposes where human beings must of necessity be in attendance about it seriously endangers its purity, rendering it unfit for human consumption," declared the Washington Supreme Court in the recent case of City of Raymond vs. Willapa Power Co., 167 Pacific Reporter, 914.

Accordingly, the court rendered the decision that plaintiff city, having acquired the right to use the waters of a stream in operating a water-supply plant, was entitled to enjoin defendant from interfering with this right by impounding the waters of the stream above the city's intake for use in developing electricity, although the waters were returned to the stream by defendant company.

Pitch as a Fuel for Power Generation

By JOHN B. C. KERSHAW

A summary of the most recent patents and experiments relating to the use of coal-tar pitch as a fuel for steam boilers and for internal-combustion engines.

THE great increase in the number and capacity of the byproduct coke ovens in the United States and in the number of works for the distillation of coal tar (in order to obtain "toluol," the chief raw material for explosive manufacture) has led to an overproduction of pitch and to accumulations of this material in all tar-distillation works. This overproduction will continue when peace is declared and the demand for explosives falls to its normal level, for the products of tar distillation will then be absorbed in the organic color industry.

In the past, coal-tar pitch has been employed chiefly as a roofing, waterproofing and paving material, its comparatively low melting point and high percentage of volatile hydrocarbons having prevented its use on any considerable scale as a fuel, with the one exception of its application as a binding agent in the manufacture of anthracite briquets.

The increase in the output of pitch in the United States during the war and the fact that over two million tons of this solid hydrocarbon is now produced annually in the tar-distillation works of the country have led to a revival of interest in the possibilities of pitch as a fuel, either for burning in the solid state under steam boilers or for use in the liquid state in internal-combustion engines.

CHEMICAL PROPERTIES OF PITCH

Before dealing with the practical methods of utilizing pitch as a fuel, it will be advisable to review briefly its chemical and physical properties, since the question of its successful application as a source of motive power hinges largely upon a correct appreciation of the difficulties attending its proper combustion, either in the solid or the liquid state.

When coal tar is heated in the usual type of 20-ton still in order to separate and recover the more valuable constituents, with boiling-points below 270 deg. C., there remains in the still a residue known under the trade name of pitch.

Chemically, pitch is a mixture of hydrocarbons containing oxygen, nitrogen and sulphur. The constitution varies with the source of the tar and also with the temperature to which the distillation has been pushed in order to recover the oils of lower boiling point. One ton of an average tar under ordinary conditions of distillation will yield the following products: Benzol, ⅓ gal.; toluol, ⅔ gal.; solvent naphtha, 1½ gal.; heavy naphtha, 1 gal.; carbolic acid (crude), 2-3 gal.; crude cresylic acid, 2 gal.; creosote oils, 20 gal.; anthracene oils, 34 gal.; naphthalene, 112 lb.; pitch, 10 cwt.

The light oils distill at a temperature below 170 deg. C., the carbolic or middle oils at temperatures lying between 170 and 230 deg. C., and the heavy or creosote oils from 230 to 270 deg. C. The anthracene oils come over only at higher temperatures (from 270 to 400 deg. C.), and the distillation is not always carried so far as to remove these oils entirely from the pitch. A large portion of the pitch, 10 to 50 per cent., consists of finely divided carbon, but from 50 to 90 per cent. consists of solid unsaturated hydrocarbons of the aromatic type, which give the pitch its distinctive properties. According to Martin, the elementary analyses of hard and soft pitch yield the following: Hard pitch, 93.2 per cent. carbon, 4.4 per cent. hydrogen; soft pitch, 91.80 per cent. carbon, 4.60 per cent. hydrogen.

The calorific value of pitch is extremely high; a sample tested by the writer in the bomb type of calorimeter having shown 15,928 B.t.u., or a higher value than that of the best Welsh steam coal. This high calorific value is, however, counterbalanced by the production of a high percentage of volatile hydrocarbons when it is heated, the following being an approximate analysis of a north-country pitch: Moisture, 0.05 per cent.; ash, 0.60 per cent.; volatile matter, 66.85 per cent.; coke, 33.15 per cent.; fixed carbon, 32.55 per cent.

ITS PHYSICAL PROPERTIES

As regards the physical properties of pitch, the specific gravity varies from 1.20 to 1.35, the hard pitch produced when the distillation of the tar has been carried to a high temperature having the higher specific gravity.

The melting point likewise varies within wide limits, but it must be noted that the term melting point when applied to pitch is an arbitrary one, since the material when heated gradually softens and passes by almost imperceptible stages into the liquid state. The limits of melting point noted are 37½ deg. C. in water and 174 deg. C. in air, but a pitch melting at 37½ deg. C. (100 deg. F.) would hardly deserve to be classed as a pitch, since this low melting point would signify that the distillation had only been carried far enough to drive off the water, lighter oils and some portions of the carbolic oils.

Pitch, as shown by the analyses previously given, is composed chiefly of free carbon and of hydrocarbons which become volatile on heating above 400 deg. C. It is therefore combustible and under proper conditions can be burned to CO_2 and H_2O vapor, with the production of heat equivalent to 15,900 B.t.u. per lb. of pitch consumed. The very high percentage of volatile hydrocarbons which are evolved when it is heated above its melting point, however, renders it difficult to burn pitch without the production of smoke, for even if the problem of keeping the air supply adequate for the proper combustion of these hydrocarbon gases be solved, there is still the difficulty of securing a proper admixture of the air and of the evolved combustible gases. These gases also are liberated at a lower temperature than in the case of bituminous fuel, and this signifies that they require further heating before they reach the ignition point, otherwise they may escape from the furnace unconsumed, without yielding any of their heat value. This analysis of the difficulties of burning pitch as a solid fuel under steam boilers shows that special arrangements are necessary and that it is useless to simply shovel the lumps of pitch mixed with the coal into the furnace and expect good results from the mixture.

In fact, when such attempts are made to burn pitch in the ordinary furnace under Lancashire steam boilers, the pitch softens and melts, and closes the air spaces in the grates before the liberation or the ignition of the gases has occurred. Dense volumes of black smoke are therefore produced by this cutting down of the air supply at the time when a large excess of air is required for efficient combustion, and the fire side of the tubes of the boiler and economizers becomes covered with a thick, oily deposit of soot, which enormously reduces the transmission of heat to the water. The hydrocarbons contained in coal pass from the solid to the gaseous state on the application of heat without assuming this intermediate or liquid stage, and for that reason coal is much more easily burned than pitch.

The conditions required for burning solid pitch are therefore three in number: An adequate supply of air, above or through the grate; an adequate admixture of this air and the evolved gases, and means for raising this large volume of air and hydrocarbon gases quickly to the ignition point of the latter.

Burning Pitch Under Lancashire Boilers

The managers of certain gas works are reported to have solved the problem of burning pitch under Lancashire steam boilers, with the aid of forced draft and a special type of channeled solid fire-bar, known as a pitch-bar.

Some of the ordinary fire-bars of the furnace are removed, and the pitch-bar substituted, the number and distance apart of the latter depending upon the character and volatile matter contained in the fuel that is being consumed on the other portions of the furnace grate. The pitch, broken to a convenient lump size, is fed onto the front end of these special pitch-bars, preferably by some type of mechanical feed, which will maintain a regular supply without opening the furnace door. The heat of the surrounding fire causes the pitch first to melt and to flow down the channel of the bar and then to volatilize. The rate of such volatilization is said to be controlled by the form of the bars, and the forced draft supplies the surplus-heated air which is required to secure the combustion of the hydrocarbon gases produced from the molten pitch. The partly coked residue which remains after the more volatile constituents have been driven off and burnt, is then pushed to the rear portion of the grate, where its combustion as ordinary coke offers no special difficulties. Details of this method of burning have been published.[1]

Pitch is also being burned in a tar-distillation works in the North, in conjunction with breeze and coal under Lancashire steam boilers, in the proportions of 75 per cent. breeze, 18 per cent. pitch and 7 per cent. coal, without any trouble from smoke. The boilers in this case are hand-fired and work under natural draft. It will be observed that the proportion of pitch is only about one-sixth of the total weight of fuel used, and as the breeze evolves only a comparatively small amount of hydrocarbon gases, the final volume of combustible gas to be consumed is not large.

At one time a mixture consisting of 45 per cent. crushed pitch and 55 per cent. breeze was employed. The steam-raising value of this mixture was good, but it produced smoke, and in time resulted in an oily deposit of soot on the economizer tubes. This deposit could not be removed by the scrapers and eventually had to be burnt off. Probably if forced-draft apparatus had been installed with a preheated air supply, this half-and-half mixture of pitch and breeze could have been burned without any trouble, since a deficient air supply was undoubtedly the cause of the sooty deposit.

The possibilities of using pitch as a liquid fuel under steam boilers do not appear to have been yet investigated upon a practical scale, although this method of employing pitch would probably prove the most efficient and the least costly to work when once the necessary apparatus had been installed. The distillation of the tar in this case would be stopped when the light and middle oils had been distilled (that is, at 200 deg. C.) and the soft pitch which remained in the still would be utilized in the semi-liquid state in a modified form of the usual atomizing injector, using superheated steam or hot air under pressure, as motive power. The preheating of the air supply and the thorough admixture of the minute globules of liquid pitch and the air could be most effectively carried out by this system of combustion, and since coal tar has already been utilized successfully in this way, the atomizing of a material that is only slightly more viscous at ordinary temperatures would not offer insuperable difficulties.

In this connection the patent of Arnold Philips, an Admiralty chemist at Portsmouth, England, for reducing the viscosity of thick oils, may be referred to. In this patent (No. 14,778 of 1913) the addition of 8 per cent. of naphthalene is specified for rendering certain thick oils more suitable for fuel purposes. If the naphthalene be left in the pitch, it is reasonable to suppose that it will also have the same effect in rendering the latter more suitable for atomizing purposes. Should difficulties from cooling and partial solidification occur in the spraying nozzle, these no doubt will be overcome by inclosing the latter in a heat-insulating jacket, through which the preheated air or superheated steam would be passed before entering the atomizing nozzle.

Recent Patents Dealing With the Subject

As regards recent patents dealing with this subject English patent No. 101,444 of 1916, granted to G. H. H Bölling, of Christiania, describes a method of melting the pitch by means of the heat of a steam coil and introducing it through similarly heated pipes into the furnace, where it is atomized by a jet of steam or air. The steam jackets, pipes and valves are so arranged that any incrustation may be removed. German patent No. 290,708 of 1914, granted to Robert and Trinyi, relates to the similar use of powdered pitch as a fuel, the pitch in this case being blown into the furnace in the form of dust. Finally, the English patent of G. Heyl (No. 110,023 of 1916) may be referred to, according to which liquid fuels suitable for firing furnaces and for use in high-compression oil engines, can be manufactured with the aid of pitch, by treating mineral oils and heavy creosote oils with solid caustic soda, to neutralize the acids present and to remove sul

---

[1] "Chemical Trade Journal," Nov. 4, 1916.

phur compounds. The oil is cooled to eliminate the naphthalene (a mistaken proceeding in the light of Philips' discovery) and is then heated with pitch. It is stated that up to 50 per cent. of the latter by weight can be dissolved by this method of procedure.

One method of rendering pitch sufficiently fluid to be used in internal-combustion engines is described in the foregoing, and it is highly significant that the Controller of the Mineral Oil Production Department of the Ministry of Munitions is now arranging for trials of mixtures of pitch and creosote, in order to test their suitability for this particular purpose. The writer has been informed, however, by an electrical engineer who has had some experience in the use of such mixtures for Diesel engines, that used in the ordinary way they are not very satisfactory, owing to starting difficulties and to incomplete combustion in the engine cylinder. When burned, however, with the aid of a pilot ignition apparatus, they give quite good results. With this apparatus 5 per cent. of petroleum oil is injected into the cylinder just before the creosote and pitch mixture enters, and this pilot charge of a more easily ignited oil enables the temperature to be kept sufficiently high to obtain proper combustion of the composite heavier oil.

The chief difficulty in using heavy oils in gas engines is of course to prevent imperfect combustion, and the consequent choking of valves, etc., with carbon. Should this occur, the use of a mixture of wood alcohol and ammonia has been used for removing these deposits without the application of heat, but the writer is unable to state whether this mixture has proved satisfactory in practice. Burning off, the usual plan, is of course efficacious, but it is troublesome, and a liquid agent which would act in the cold would have much in its favor.

PROGRESS IS BEING MADE

This summary of the most recent patents and experiences relating to the use of coal-tar pitch as a fuel for steam boilers and for internal-combustion engines, shows that some progress is being made. The methods of rendering pitch sufficiently fluid to be used in atomizers are in the opinion of the writer the more hopeful, and he is less confident that pitch can be used economically in the solid and pulverized condition for firing steam boilers.

The fact that pitch softens at a comparatively low temperature means that the heat generated by friction in the pulverizing apparatus will have to be dissipated by artificial cooling, to prevent the grinding surfaces becoming clogged with half-melted pitch, and this artificial cooling must add considerably to the costs of the grinding operation. In the methods of rendering pitch more fluid, the heat added to the material is of direct service later in accelerating and improving the combustion in the boiler furnace or engine cylinder; consequently, the heat is not wasted, but is preserved and made effective at a later stage of the combustion process.

It would seem, however, a waste of time and heat energy to first separate the constituents of coal tar by distillation into four or five separate portions and then to recombine some of these portions in order to obtain a mixture suitable for use as a liquid fuel. The writer considers that the future line of development will be to carry the distillation only far enough to win the lighter oils and the phenols from the raw tar, and that the residue from the stills, containing the heavy creosote oils, the naphthalene and the pitch, will be sold and utilized as a liquid fuel. The anthracene oils, which are the last constituents of the raw tar to distill over (270 — 400 deg. C.), would in this case be left in the pitch, and only when the demand and price offered for the anthracene made its extraction profitable would the complete distillation of the raw tar and separation of all the possible classes of its constituents be carried out.

The Use of Metallic Gaskets

BY W. B. HAYNES

When a gasket of any description is offered to you with the assurance that it will stand air, oil, gas, water, steam of any temperature, expansion and contraction, electrolysis, etc., you smile sweetly, and while you try to be polite and say "very interesting," it occurs to you that someone has a lot to learn about gaskets. Let me set down my belief regarding metallic gaskets, their uses and limitations, reserving the right to change my mind on these points if I am wrong.

The ordinary corrugated copper gaskets are approximately $\frac{1}{64}$ in. thick and are generally used as a ring inside the bolt circle, and two in a joint, because when only one is used the flanges are apt to spring enough under the strain of the bolts to touch, iron to iron, outside the bolts, permitting a leak. In other words, one thin copper gasket is not enough for the ordinary commercial flanges to "get a bite on." When two gaskets are used, they should be meshed the same way of the corrugation. Metal gaskets should be coated with pipe cement, graphite and oil, or lead and oil, and bolted up before the coating has dried, so that each corrugation flattening under the pressure forces a ring of this filler concentrically around the flange, and the copper gasket practically acts as a binder. There are, however, exceptions to this rule of two gaskets, especially on low-pressure work. Copper gaskets should be annealed soft and pliable, as the final process, because in the process of corrugating it becomes hard, stiff and springy. This is because in corrugating, the fibers of the metal are strained and thrown out of harmony and mesh. Annealing brings these fibers back into harmony and restores the strength of the metal, therefore always mark orders for soft gaskets "to be annealed after making."

A steam-fitting contractor doing bad work, if he only wants to "get an acceptance of the job, get his money and get out," looks with disfavor on gaskets of the thin variety because he has to do a good job to get an acceptance.

The ideal gasket is one that covers the pipe ends as well as the flange, if the pipes are faced off flush with the flange, because such a gasket will save thread leaks. If, however, the pipe does not come out flush with the flange, this cannot be accomplished with any gasket. The following trite saying of a purchasing agent is worth repeating: "We have joints in our power plant that cannot be opened for replacing gaskets for a less cost than ten dollars. We cannot, therefore, afford to put in a poor gasket as it is putting on a mortgage that will be foreclosed with a blowout."

Conditions in the Power Industry

BY L. W. SCHMIDT

A digest of the reports of United States consuls on the power situation in various parts of the world and the influence of the war on this important industry. Also see "Power," June 4, 1918.

BY ENFORCING increased economic activity over practically the whole world, the war has widened the field of electric power. Lack of man power has probably been the principal factor in this development, but there is plenty of evidence that electric power will be used after the war in many places where before it was only in the experimental stage. The report comes from England (C. R. 78)[1] that extensive use may be made in agriculture of the so-called electrification of crops, which consists in exposing growing crops to electric light. This treatment adds largely to the productive power of the plants according to extensive experiments made before the war. There has been formed in England the Electric Discharge Co., which enterprise intends to treat not only growing crops, but also the seeds. Plants for the treatment of seeds have been erected at several places in England, and it is said that the increase in the yield from seeds so treated is between 25 and 80 per cent.

WIND MOTORS FOR CHEAP POWER

If the method generally proves successful, it will open a new field for the power industry. Cheap power, of course, will be needed for the purpose, and it has been suggested that electric power generated by wind motors be used for the purpose of crop electrification. The argument in this case is that power generated in this way costs practically nothing beyond the expense of the installation and its upkeep, and that any power that can be obtained by wind comes handy for crop treatment, since there is no need for maintaining a regular supply of power.

England feels more and more the effect of the high cost of living on power production. Following the example of other cities, Birmingham has increased the cost of electric power to consumers. The rate of increase affects both light and power and amounts to between 10 and 15 per cent. To prevent electrical consumers from changing over to gas consumption and so putting undue stress on the gas works of the city, the municipal authorities also have raised the gas rates (C. R. 81).

Much of the increased cost in the power stations has been caused by the rapid rise in wages necessitated by the corresponding increase in the cost of living. Nearly all private and municipal enterprises have been compelled to add to their wage scales, and recently it became necessary to increase the wages paid to the employees of the Nottingham tramway corporation, following arbitration by the Ministry of Labor. About 450 employees of the corporation were affected by the decision (C. R. 83).

Italy has just taken a step that has already been taken by several other countries in the war and that may become necessary in this country. It has made an exact census showing the unemployed machine power of all kinds that may be put to use when needed. The census includes locomotives, boilers, motors, power plants and general power machinery. The forms that had to be filled out by the owners of the machines specified the kind of fuel necessary and the number of workmen employed in running the machines (C. R. 82). Germany made such a census in 1915 and many motors and other power machines have been transferred from parts of the country where they could not be employed to advantage to districts where there was an urgent need.

LONGEST TRANSMISSION-LINE SPAN IN WORLD

In a preceding article[2] on this subject, mention was made of the work done on the new power transmission line from Florli to Stavanger in Norway and the erection of the power plant at Florli. The transmission line is now ready, and the power plant will be completed in the near future. In that way 12,000 hp. will be made available for the Stavanger Electric Co. Incidentally, the erection of the transmission line involved crossing the Hogsfjord by a single span of 1514 yd., which is said to be the longest in the world. The span is composed of three cables of crucible steel, since copper or aluminum would not be able to stand the strain. Copper-sheathed cable would have been preferable to prevent loss of voltage, but under present conditions it could not be obtained. Each cable has a diameter of 0.63 in., is composed of 19 strands and has a tensile strength of about 210,000 lb. per sq. in., or a total of about 25 tons for the whole cable. The slack of the cable is 87.5 yd. and in a strong wind it will oscillate 54.7 yd.

The effect of the new installation has begun to show in the neighboring cities, especially in Stavanger and Haugesund, by an increase in the demand for electric installations. Electric current is used quite generally for domestic purposes, and Consul Henry C. A. Dunn, in Stavanger, advises American manufacturers of great sales opportunities in the district (C. R. 104).

DENMARK BEGINS ELECTRICAL DEVELOPMENT

The rapid development of the natural-power resources of the northern Scandinavian countries also exerts its influence on Denmark. Not only is this country buying electric power from its northern neighbors, but it has also begun to develop some of its own. Denmark has little water power available, and to provide cheap electric power it may become necessary to use the great peat beds. These are situated in the western part of the country and will be developed as soon as the necessary capital can be found. In the meantime steps have been taken to make use of 1000 hp. of water power from the Gudenaa, a small river near Aarhus. The cost of this development is estimated to be approximately $1,000,000, and it will be a year before the plant can be put into operation (C. R. 72).

---

[1] C. R. indicates "Commerce Reports" of 1918.

[2] "Power," Dec. 11, 1917.

Another country which has felt heavily the effect of the war, although remaining neutral, is Switzerland. It is a peculiar fact that Switzerland, having possibly the best natural-power resources of the world for so small a territory, has until recently made very little use of hydro-electric power. For many years gas has been the mainstay for street lighting in many cities. Now the difficulty of obtaining coal has impressed upon the Swiss communities the necessity of making better use of the nearer and cheaper resources at home. So the consumption of electric power is growing rapidly in Switzerland, and during the last year most of the existing stations have reported increasing demands on their producing capacity. The result is that it is now contemplated to enlarge the existing stations and to add a number of new ones in the near future, so as to make Switzerland increasingly independent of foreign coal.

Future Industrial Activity in Spain

After the war, and possibly even now, Spain should attract the attention of our power specialists looking for foreign investments. Spain is an industrially active country which in the future will play a considerable part in the production of many commodities of the cheaper kind. Cheap electric power will be necessary for that purpose, but the numerous schemes now under way may come to nothing owing to the lack of capital. This will have to come from the outside, and America should be able to supply it together with the necessary machinery and equipment.

Vice Consul Asel D. Beeler writes from Bordeaux about the great resources of the Pyrenees. What he says about the French side of the mountain range applies also to the southern side. "The mountain region is supplied abundantly with swift and powerful currents of water, readily adaptable to the development of hydro-electric power, a desirable feature where the coal supply is limited. Many of the industries of the cities in the Pyrenean country, as shoe factories, woolen mills and railways, are now operated by electric power which is abundant in a considerable area of the Midi section. The general development and industrial utilization of electric motive power is more characteristic of the industry in the departments of Basses- and Hautes-Pyrenees where the most railroads, the largest rivers and the most populous cities are."

Developments in French Pyrenees

On the French side of the Pyrenees, on the Ariège River near Las Mijanes, a power plant of an average development of 2500 hp. is being erected. The owner of this enterprise is the Société Métallurgique de l'Ariège which recently bought the stock of the Société Hydro-Electrique des Pyrénées, owning a plant at Castelet with a waterfall 90 ft. high and permitting the installation of four turbines of a capacity of 800 hp. each (C. R. 92)). The company also owns rights to develop power on the Nagear, where there is a waterfall of 1200 feet.

The City of Sofia, in Bulgaria, intends to build an electric central station, although it is doubtful whether American power interests will feel much inclined to make use of an opportunity to extend their connection in that field just now.

By cutting off the usual supplies reaching South America from European countries, the war has forced industrial expansion everywhere in Latin America, with the result that there has been an increasing demand for electric power. This has been supplied by extending existing enterprises and by adding a number of new ones. During the last few months several of the leading power enterprises in South America have made their annual reports, which in each instance seem to show a considerable expansion in power distribution and also increased takings.

One of the most representative enterprises, doubtless, is the Lima Light, Power and Tramways Co., of Lima, Peru. This company reports a gross revenue of $2,142,480, as against $1,986,360 during the year 1916. The net revenue amounted to $964,250. There has been, however, a noticeable rise in the yearly expenses amounting to $76,740. Increased employment of electric power is given as the chief reason for this good showing and also an increase in the tramway traffic. High cost of materials, which in many cases had to be imported from the United States at any price, has added largely to the increase in operating expenses. The company made several extensions of its plant during the year 1917, which included the installation of a 2500-hp. turbo-generator and a 2000-hp. Babcock & Wilcox boiler. New installations have been made at Chosica, Yanacota, Barranco, Chorillos, Miraflores and Lima (C. R. 105).

Increased Rates for South American Plants

In Chile electrical enterprises have been suffering much from the lack of coal. Several Chilean power plants are burning wood, which is cheaper than coal. The scarcity of fuel and its high price have forced most of the power plants in South America to increase their rates, and this action has not always been accepted in a very friendly spirit by the consumers, already exasperated over the high cost of living.

In Uruguay the government has just authorized the governmental power plants to increase their rates. This step is explained to the public principally on the ground of increased cost of fuel. Many Uruguayan power plants, by the way, are burning oil imported from the United States (C. R. 96).

The exceptional activity in the power industry reported from other parts of the world has also been noticeable in eastern Asia and India. In Japan it has found expression in an increased demand for hydro-electric power, which doubtless has been caused by the high prices that had to be paid for coal. The rising operating cost, however, so far has not allowed the hydro-electric power companies to take full advantage of the situation, with the result that so far none of them report materially increased earnings.

In China the electrical industry is suffering a good deal from the lack of new machinery. The demand for new installations is great, but as it is practically impossible to get new machines, repair work and additional construction are much delayed. This condition is leading to an increase in the manufacture of power machinery in China, especially in Hongkong—a piece of news which doubtless will interest American manufacturers. If it should turn out that Chinese and other Asiatic concerns get into the habit of building complicated power machinery in their own plants during the war, they may continue the practice after the war, with the result that much trade will be lost to American and European manufacturers of such machinery. This is one of the dangers caused by the present interruption of foreign trade. However, it is not probable that a Chinese machine-building industry much better developed than that which now exists will be able to meet the demand for power machinery which is to be expected from China in the near future. Even with such national competition, therefore, there may be expected a healthy demand from that country after the war.

In both Hongkong and Shanghai, by the way, a considerable increase in takings is reported by the local tramway companies. The Shanghai Street Car Corporation, which in 1909 carried 11,750,000 passengers, is now carrying 73,500,000 per year, and its takings have been trebled. Electrical engineers in China are of the opinion that the future of electrical enterprise is extremely bright. Proposals are now made for a more scientific development of the existing opportunities and also for the creation of machinery which later will allow the linking up of existing systems so as to make them mutually supporting (C. R. 89).

In Madras, British India, there are at present 54 industrial establishments operated by electric power. The total sale of current, which amounted to 5,086,609 units during 1916, has now reached 5,693,807 units, and the increased demand for energy has led to the erection of two new substations. There are today 126 electric plants in operation in the Madras Presidency.

Causes of Vacuum Trouble

By L. F. Forseille

Previous to the application of the little device herein described, considerable trouble was experienced at times in maintaining a normal vacuum on a 10,000-kv.-a. turbine unit equipped with a jet type of condenser.

The small turbine driving the air and removal pumps is loaded to its maximum capacity, thereby affording very little reserve for any additional effort that it might be called upon to exert. After carefully watching its performance, I found a number of causes of the trouble, each being accompanied by a partial loss of vacuum, the extent of this loss being governed by the time required by the attendant to correct the trouble. The most frequent causes were obstructed strainers in the air-pump supply line. These instances were invariably preceded by racing of the pump turbine.

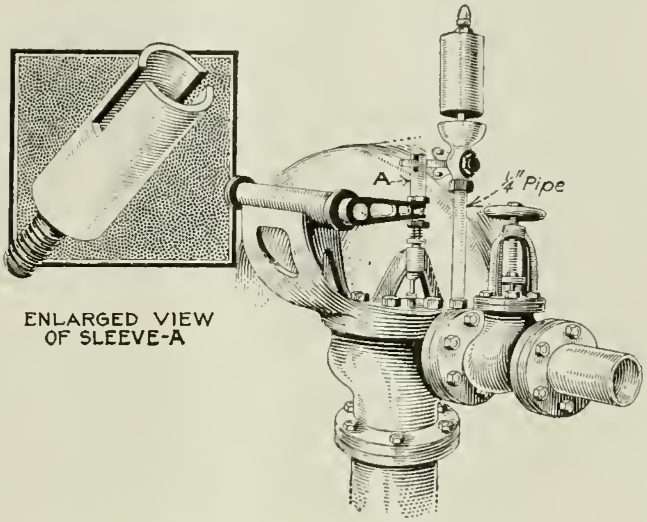
Following is a list and a brief explanation of each of the contributing causes:

Too much injection water being used, thereby overloading the pump turbine.

A sudden reduction of load on the main unit would immediately result in the turbine racing. This I believe can be accounted for as follows: A reduction in load will result in a rise in vacuum, increasing the velocity and consequently the amount of water entering the condenser. This is further augmented by a drop in temperature of the discharge water and an increase in the working head. Summing up the different changes that take place, I believe that the reduction in the amount of steam flowing to a condenser is more than compensated for in the increased amount of injection water, leaving the pump to discharge as much, if not more water, than with a full load on the main unit, and this at a greatly reduced temperature. This latter item must be considered, owing to the fact that the discharge is approximately 18 ft. above the center line of the pump. Of course the only remedy, as in the preceding case, is to cut down on the injection water. Too much water going to the air pump has about the same effect and can be overcome only by cutting down the amount.

Obstructed strainers in the air-pump supply line will cause the turbine to race violently. This, I think, is caused by the pump alternately picking up slugs of water and air. The remedy is to change over to the clean strainers.

Wet steam coming over from the boilers will cause racing and a momentary loss in vacuum, which usually rights itself without any further trouble. However, in extreme cases it is necessary to cut down on the injection water until the trouble has passed, when it can be gradually brought up to normal volume.



ARRANGEMENT OF SIGNAL WHISTLE

A vacuum leak in any part of the system, including the water-supply line, will also cause racing, and if serious, racing will continue until the leak is stopped. It will be noticed (as I have previously mentioned) that any irregularity in the pump turbine is a sure sign that something is wrong. On the other hand, as long as the turbine is going smoothly one can rest with a fair degree of certainty that this part of the equipment is working all right. This fact became so apparent to the attendants that they formed the habit of watching the governor arm on the pump turbine at all times when not actually engaged in performing their other duties.

The apparatus mentioned in the beginning of this article simply acts as a warning to attendants and can be heard from any part of the turbine room or basement. It consists of a small whistle screwed into the top of the governor valve and actuated by the governor arm (see illustration). It has been in operation about a year, and the results have been most gratifying, so good in fact that the vacuum on this unit has not been lost since from any of the foregoing causes, due to a timely warning and good work by the attendants. It is so constructed that it can be adjusted to sound an alarm whenever the governor arm comes within any desired distance from the stop. The sketch is self-explanatory.

Yarway Adjustable Spray Head

When cooling water for condensing purposes can be obtained from a convenient river or lake, there is no necessity for installing means for cooling it. But when the supply is limited, so that it is necessary to use the water over and over again, artificial recooling must be employed. There are two common methods of cooling circulating water—one by means of cooling towers, the other by means of cooling ponds in which the water is stored after passing through a number of spray nozzles that break up the water that comes to them under pressure.

In Fig. 1 is shown a spray pond[1] the spray nozzles of which are adjustable. They are known as the "Yarway" adjustable spray heads and are manufactured by the Yarnall-Waring Co., Chestnut Hill, Philadelphia, Penn. Details of their construction are shown in Fig. 2. The distinctive feature of this spray head is that it is adjustable with regard to the fineness of the spray obtained at any given pressure. Therefore it can be set to secure the maximum cooling range under any condition of temperature or humidity, for a minimum loss of water by driftage due to wind and for maximum efficiency of partial loads. Because of these features the full area of the pond can be used with all of the nozzles nearly closed, Fig. 1, before it is necessary to cut any of them out of service.

Referring to Fig. 2, the head consists of a cast-iron body *A*, in the top of which a 3¼-in. o. d. bronze tube *B* is secured which carries a cap through the center of which the stem *D* passes. A helical opening of coarse pitch is cut in the tube *B*, the water to be sprayed leaving the nozzles through this slot. The opening is cut at an angle of about 60 deg. with the axis of the tube so that the water is thrown upward at the same angle.

The rod *D* is adjusted to the cap *C* by a locknut *E* and moves in a close clearance brass bushing *F* that is provided in the body casting. A pin in the end of the stem engages a bell-crank lever *G*, pivoted at *H*. The lever end of the vertical arm is attached to the main adjusting rod at *J*. By moving this rod one way or the other, the stem *D* is raised or lowered, thus opening or closing the spiral slot in the cylinder *B*.

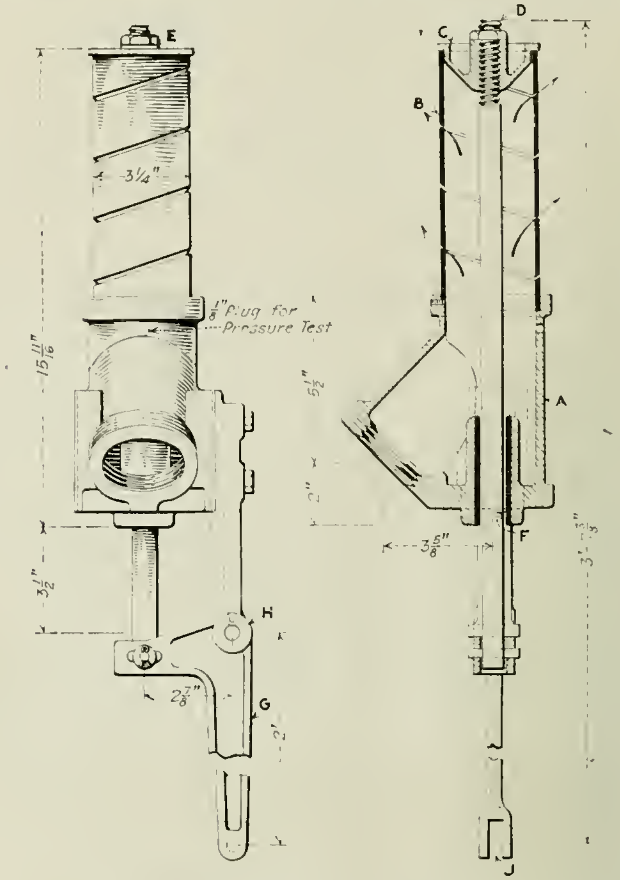


FIG 2. DETAILS OF THE "YARWAY" SPRAY HEAD

The result of this is to increase or decrease the fineness of the flow of water as it leaves the head. The water is discharged in an upwardly inclined direction in a continuous sheet which becomes finer as it spreads and finally breaks up into a uniformly fine spray or mist, or into a large number of small drops, depending upon the size of the opening to which the head had been adjusted. The method of connecting the spray-head levers to the operating rod is shown in Fig. 3.

As shown in Figs. 1 and 4, the spray heads are secured to branch pipes which connect with a main header, the branches being of succes-

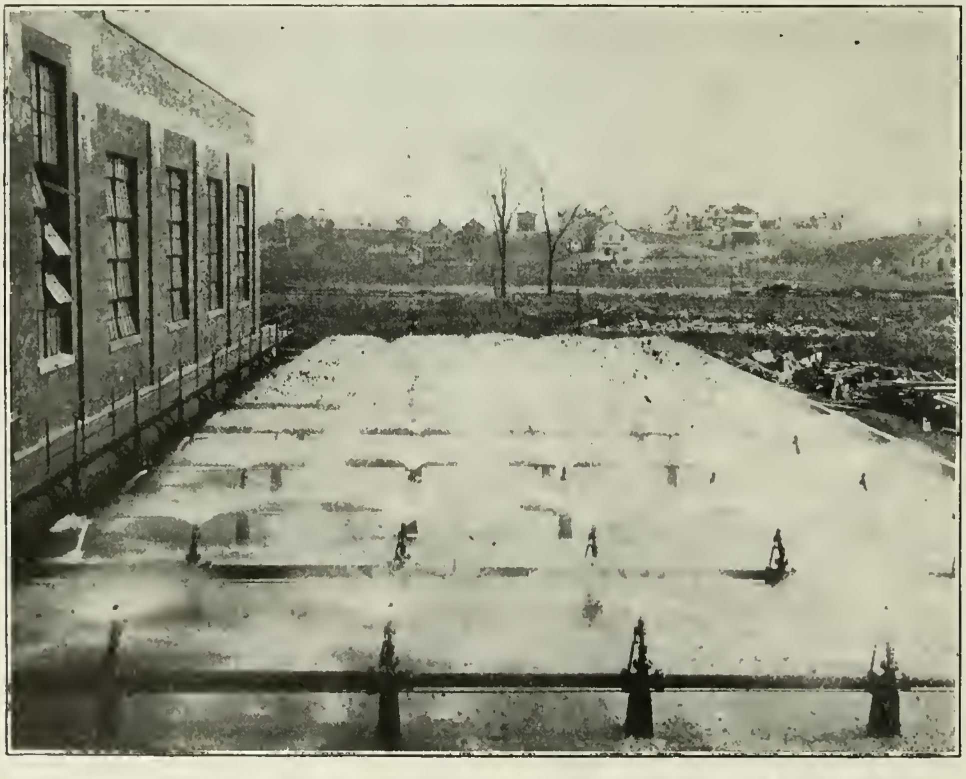

FIG. 1. "YARWAY" SPRAY-HEAD INSTALLATION, HEAD COMPRESSED

sively decreasing diameters. The adjusting lever of each row of spray heads is connected to a main ¾-in. iron pipe, to the end of which is fitted a saw-tooth regulating lever, the saw teeth being for the purpose of holding the rod for any adjustment of the spray head. This lever extends to the shore, and by a pull or a push on it all the heads in that row are either closed or opened. These rods can be seen in Fig. 4, where the spray heads are adjusted for a greater spraying capacity than in Fig. 1, where the spray is throttled. The spray pond, Fig. 4, is at the plant of the Moore Steam Turbine Corporation, Wellsville, N. Y.

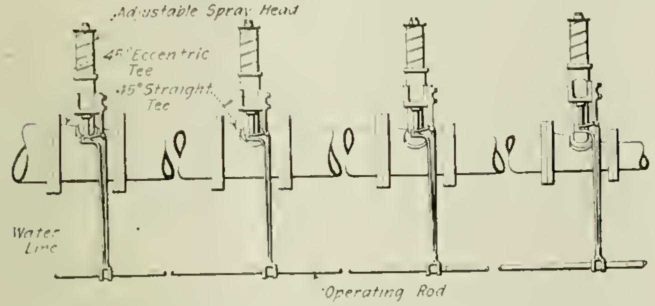

FIG. 3. ARRANGEMENT OF THE OPERATING ROD

In Fig. 1 there are shown nine spray heads with a total of 45 spray nozzles. The cooling pond is about 75 ft. wide and 180 ft. long. The main branch is 24 in. diameter and the branch pipes begin at 8 in. diameter and reduce to 4 in. These 45 spray nozzles with a 23-ft. head take care of the water necessary for condensing the steam from three 750-kw. turbines at the plant of the American Hard Rubber Co., Akron, Ohio, and are sufficient for about 35,000-kw. turbine capacity.

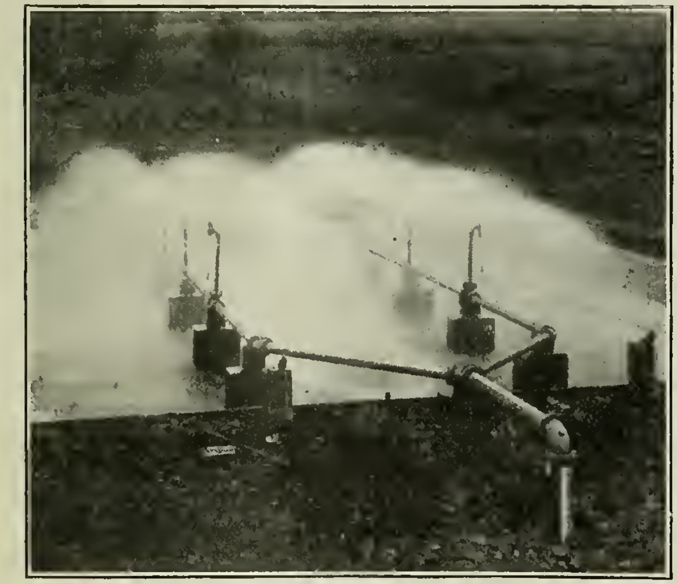

FIG. 4. A SMALL INSTALLATION SPRAYING UNDER NORMAL CONDITIONS

Gas-Engine-Valve Problems

By G. W. Muench

The buying and selling of used gas engines is a business of enormous proportions at the present time. Hundreds of these engines are bought by men who know nothing about them. A demonstration is asked for, the engine runs without knocking, and apparently everything is as it ought to be. Even the man who knows something about internal-combustion motors, however, often gets misled by one serious trouble, the valve setting. The engine may be working very well without a load or with a light load, but will not carry anywhere near full load. There are many possible causes for poor valve settings, such as wrong meshing of the gears; wrong adjustment of the push-rods; worn push-rods, cams, valve stems, gear teeth and other parts of a valve gear. The valve setting of a gas engine is about as follows:

The inlet valve should open 5 to 15 deg. past the inner dead-center and should close from 20 to 35 deg. past the outer dead-center. Exhaust valve should open about 30 to 40 deg. before the outer dead-center and should close at about inner dead-center to 10 deg. past.

Frequently, an attempt is made to make a gas engine develop a greater power than it is designed for, by changing the governor adjustment to allow the engine to operate at a higher speed. This can be done to only a limited extent. After the speed has been reached at which engines will develop maximum effort, the power of the engine will decrease if the speed is increased beyond this point. The reason for this is, the valve can take care of only a certain amount of gas in a given time, since the speed of the gases passing through the valves is limited. There is a difference of opinion as to this limit. One good authority gives the limit of the ingoing gases at 6000 ft. per min. and the exhaust gases 5000 ft. per min. These figures refer especially to stationary engines.

Assuming that the gases in the cylinder travel as fast as the piston, it is easy to figure the velocity of the gases through the valve opening as follows:

$$v = \frac{D^2 V}{d^2}$$

where v equals velocity of gases through valve passages in feet per minute, D equals diameter of cylinder in inches, d equals diameter of valve passage in inches, and V equals velocity of piston in feet per minute.

The foregoing affords a means of finding what approximately would be the speed limit of a particular engine. For example, an 11 x 12 engine having 4-in. valve openings and rated at 300 r.p.m., is to be increased in speed 10 per cent.; that is, to 330 r.p.m. The engine has a 12-in. stroke and is to operate at 330 r.p.m. This is equivalent to a piston travel of 660 ft. per min. In calculating the velocity of the gas in the valve chambers, it is assumed that in the cylinder the gas is traveling at piston speed, in this case 660 ft. per min. Then, by substituting the foregoing values in the formula, the velocity of the gases through the valve opening is

$$v = \frac{11^2 \times 660}{4^2} = 4991\,ft.$$

or approximately 5000 ft. per min.; therefore this increase in speed might be permitted, as it brings the speed about up to the allowable figures for the exhaust valve. Of course other factors enter as to the advisability of increasing the engine speed, especially the safe flywheel speed.

If the speed of an engine is materially changed, it might also be advantageous to somewhat change the valve setting. However, this may not be an easy matter, since, in many heavy-duty stationary engines the setting cannot be changed. Sometimes both valves are adjustable, but oftentimes only one can be changed. In resetting the valves, it must also be remembered that when a valve is adjusted by changing the length of the push-rods, if the valve is made to open earlier it will close later and vice versa, but if the valves are made to open and close earlier or later by changing the setting of the camshaft gear, all the valves will be affected the same in both closing and opening.

Another interesting valve problem is the division of the cycle according to the valve setting. Since it requires four strokes to complete the cycle of a 4-stroke-cycle gas engine, it is often thought that each performance of the cycle requires one stroke. This is, however, not the case. Take for example, the following setting. Intake opens 15 deg. past inner dead-center, intake closes 25 deg. past outer center; exhaust opens 40 deg. before outer center and closes 10 deg. after inner center. The complete cycle is 720 degrees. The intake opening at 15 deg. after inner dead-center and closing 25 deg. after outer dead-center is an angle of 190 deg., or about 26.4 per cent. of the cycle in suction. Between the closing of the intake and inner dead-center is the compression, 155 deg., or about 21.5 per cent. of the cycle. From dead-center to the exhaust valve opening 40 deg. before outer dead-center is the power stroke, 140 deg., or nearly 20 per cent. of the cycle. From exhaust opening to closing at 10 deg. past inner center is the exhaust stroke, 230 deg., or nearly 32 per cent. of the cycle. From this it is seen that almost one-third of the entire cycle is devoted to exhaust.

Air-Compressor Troubles

By Ray J. Bailey

Some time ago a small motor-driven vertical air compressor was installed in a certain boiler-room where there was considerable dust due to handling coal and ashes. It was necessary to extend the 1½-in. inlet pipe outside of the building. As the unloader *A* was of sensitive construction and as the least bit of dirt would make the pistons stick, causing poor regulation, considerable power was wasted because of the safety valve on the receiver releasing continually.

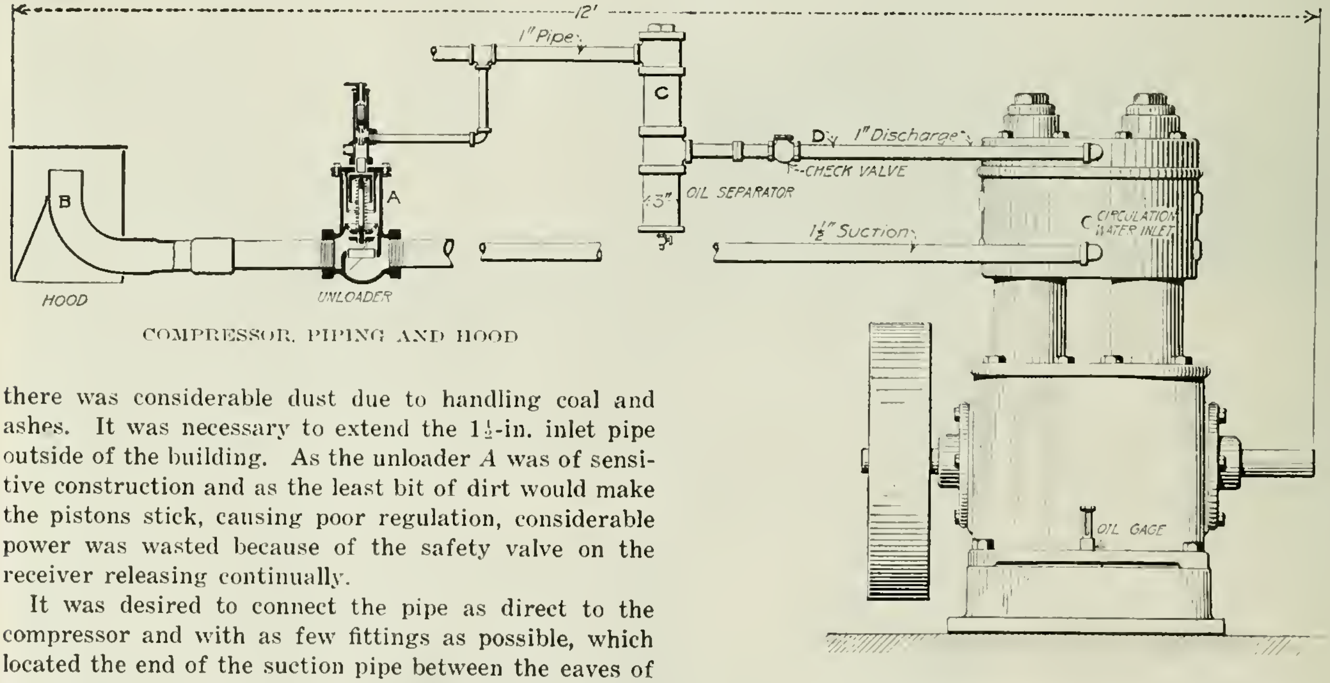
It was desired to connect the pipe as direct to the compressor and with as few fittings as possible, which located the end of the suction pipe between the eaves of three roofs. To keep it free from water and other obstructions, a hood was made, as shown at *B*, from 6-in. galvanized sheet-metal pipe with a 2-in. sheet-metal pipe on the inside soldered to a 2-in. galvanized pipe nipple. These parts were all taken from used material found about the factory. This arrangement has worked satisfactorily for nearly a year, and it has never been necessary to clean out the unloader nor has there been any trouble from poor regulation.

For lubricating the cranks, crosshead pins and pistons, four or five gallons of a certain quality of engine oil was put in the crank case when the machine was first installed. After a few days the oil was found unsuitable for this class of work, because, being thin, it would work past the pistons—which are exposed at the crank end—to the oil reservoir and about one pint per ten-hour run would pass through the valves and discharge pipe, burning on the valve stems and springs and causing them to stick and hold away from their seats. A portion of the burned oil would work into the unloader and make trouble.

An oil separator *C* was made from pipe fittings and two 3-in. nipples, each 6 in. long. A special air-compressor oil was used, and no further trouble has been experienced; less than one ounce of oil gets into the separator in thirty days.

Considerable advantage was gained by using a check valve in the 1-in. discharge pipe *D* when it was necessary to shut the machine down to examine the valves or to do work on the machine under pressure. It also serves to take the strain off the discharge valves due to the hammering effect when closing.

Several swing checks were used, which lasted but a week or ten days before the disk and seat had to be faced off and fitted so they would not leak. A horizontal globe check valve was then used, with the disk guided by a stem above and another below the seat. After being in service about four weeks, an examination showed that the stem and guide under the disk had worn away, the disk and upper stem and guide being in fairly good condition.



COMPRESSOR, PIPING AND HOOD

A check valve of the dashpot type is recommended as the best for this service, in which the upper part of the valve disk is connected to a dashpot, which will prevent its slamming.

Ethics of Sales Engineering

By WALTER G. STEPHAN

A sales engineer represents both the purchaser and the manufacturer, and although it is his business to sell, it is just as consistent with good ethics to counsel against a purchase of his apparatus when conditions are not suitable as it is to advise the purchase of his apparatus when it will supply the needs better than anyone else's. The ethics of salesmanship is discussed from various interesting angles.

THE tremendous industrial expansion in the United States during recent years has brought a most interesting and profitable field of work to the technically educated engineers; namely, the work of the sales engineer. So many new devices and improvements in the various arts have been developed that the manufacturer has gladly called into his organization men with engineering training, who have initiative, confidence in themselves and the ability to persuade others to buy and properly use new things possessing merit. As a result many able young men are successfully following this profession and securing through their work much of the satisfaction that should come to a man through a useful business life.

HIS DUTIES DIFFERENT FROM THOSE OF THE ORDINARY SALESMAN

This army of young salesmen are mostly men who wish to transact business on a sound business basis and who are following a code of ethics of their own which is more or less the result of their previous training and experience. So far as is known, there is no treatise on engineering salesmanship that covers satisfactorily the work of the sales engineer. His duties are sometimes quite different from those of the ordinary salesman. For example, occasionally he has to deal through a consulting engineer, an intermediary between his company and the ultimate purchaser, with whom other salesmen do not come in contact.

Sales experience has gradually formulated a code of ethics regarding the right and wrong way to try to sell first-class power-plant equipment, and this article is an endeavor to provoke a discussion of the subject for the benefit of the selling fraternity as well as the buying public.

The sales engineer represents two parties, each of which is equally concerned in the sale—the purchaser and the manufacturer. And he should be equally concerned to see that both receive fair treatment and that neither is taken advantage of by the other. If there is to be any preference, he should favor the purchaser, for the reason that no obstacles should be permitted to grow up in the path leading from the buyer to the sales office. The door for future business should be easy for the purchaser to open, and he should feel that it is a pleasure for him to open it.

A purchaser is naturally inclined to buy from the seller with whom it is pleasantest to do business. The same line of reasoning applies in the case of the hotel management which uses as its motto in matters of dispute, "The guest is always right." It is not meant by this that the salesman should permit the purchaser to take a great advantage in the transaction, but it is meant that if there is a reasonable question of doubt, the purchaser should be given the benefit of that doubt.

The importance of giving the buyer the benefit of a salesman's experience cannot be emphasized too strongly. It is just as consistent with good ethics for him to advise a prospective purchaser not to buy his apparatus when he knows from experience that the conditions are not suitable, as it is to advise the purchase from the company he represents when he knows he can supply the buyer's needs better than anyone else or equally as well. In fact, it is frequently found that by conscientiously advising a purchaser to buy just the right thing from a competitor, the salesman can and has immensely strengthened his hold upon the buyer's confidence.

HIS WORK JUDGED BY SERVICE RENDERED RATHER THAN BY SALES MADE

If a salesman is merely interested in selling and is not desirous of performing some real service to society, he will fail to get all he could out of his work. After all is said and done, his work will be measured by the "service rendered" and not by the sales made. The man who is concerned only with making the sale is a mere "peddler," and not worthy of the name of sales engineer. His vision is not broad enough to see the transaction from the viewpoint of the purchaser as well as from that of his firm. He sees only his own immediate remuneration and not his ultimate gain. He should be quick to recommend against a bad purchase and should just as carefully avoid a bad sale. He should seek to carry through transactions that will be mutually advantageous to the purchaser and the manufacturer.

It sometimes happens that, notwithstanding a conscientious recommendation against the purchase of a sales engineer's apparatus, for apparently good and sufficient reasons, conditions obtain later which would have justified the sale. For example, the entrance of the United States into the present war has already changed conditions in many plants beyond the imagination of the most astute business minds. In such instances the salesman can console himself with the knowledge that he followed the dictates of his best judgment.

It sometimes happens that an operating engineer learns that one of the plants in his neighborhood is about to purchase certain equipment. Knowing that a certain salesman's machinery has given him splendid service and wishing to help both his neighbor's plant and himself, he offers to assist in making a sale, provided the salesman is willing to pay him for such service. It is a question of ethics whether it is right to agree to do this. If the engineer can conscientiously recommend the apparatus, he is honestly entitled to remuneration for his assistance in selling. However, it is much better for all concerned not to enter into such negotiations. The danger lies not in this transaction, but in possible future affairs. Some subsequent negotiation may come up between the engineer's company and the salesman for a purchase, which will embarrass one or the other and will make the engineer feel under some obligation to buy from the salesman whether it be fully to the advantage of his employer to do so or not.

Whenever it becomes necessary for the manufacturer's representative to sell through the office of a consulting engineer, other problems present themselves for solution along ethical lines. It is taken for granted that when a manager employs a consulting engineer to build or extend his power plant, he delegates him to recommend what kind and make of apparatus is to be bought. In other words, he says to the consulting engineer: "I don't know a thing about boilers, stokers, engines or turbines. You do. Tell us what we should buy and see that a plant such as we will need is built."

His Statements to the Consulting Engineer Should Be Perfectly Frank

The consulting engineer, in preparing specifications for bidders, sometimes calls in several sales representatives in order to discuss the specifications with them or the limiting features of his plant and to make sure that the work of the various contracts will join together to make a complete whole.

Under such circumstances the salesman will find a perfectly frank statement from him to be most acceptable to the broad-minded engineer. If he finds that the consulting engineer is making inadequate provisions anywhere or that his apparatus is not suited to the conditions, a free discussion of the matter will be appreciated. To a certain degree the consulting engineer is somewhat analogous to the general practitioner in medicine, and the experienced salesman corresponds to the specialist. He is, therefore, the specialist or one of several specialists. Very few consulting engineers are buying all kinds of power-plant equipment so continuously that they are able to keep strictly "up to the minute" on the latest developments in the art. The salesman is, or should be, one of the best-posted men in his line, with some such motto as this before him:

> "If a cobbler by trade, I'll make it my pride
> The best of all cobblers to be;
> And if only a tinker, no tinker on earth
> Shall mend an old kettle like me."

A salesman should not endeavor to see that the engineer's specifications are so worded as to give him great preference or advantage in the bidding. Specifications should be written so as to exclude such articles as are not suited to the plant and should permit of a choice by the purchaser between not less than three reputable manufacturers, if possible. Honest competition hurts no one, and if an apparatus can't stand on its own merit in fair and open comparison, don't waste time trying to sell it. Life is too short.

Going Over the Engineer's Head

There is great temptation, after specifications have been issued by the consulting engineer, for the salesman to seek an interview with the ultimate purchaser in order to secure additional influence in favor of his equipment. This is commonly called "going over the engineer's head" and, naturally, is resented by him. The only ethical way to proceed, if there is any reason whatever for desiring to talk to the man who will finally sign the order, is to go to the consulting engineer, state the case frankly and take his advice. While in some cases one may be able to secure business by going over the engineer's head, it certainly will not help to get further specifications to bid upon from the engineer's office. Consulting engineers are just as human as are others.

If for any reason it becomes evident to the salesman that he is repeatedly being discriminated against by the engineer's specifications, and he has endeavored courteously on several occasions to dissuade the consulting engineer from this course, then there is no further reason for avoiding an interview with the ultimate purchaser in which can be stated diplomatically but frankly the reasons for taking such a step.

The most difficult problem for the sales engineer is undoubtedly the prospective sale to a municipality. Most men "hate a municipal job." The reason for this is that so many incompetent persons are usually concerned with the municipal purchase, and so many conflicting interests are involved, that there is no reasonable probability that the best bidder will get the contract. Boards of public service composed of several men and sometimes councilmen in addition, interest themselves in a large contract for power equipment—and very properly so—but they do not leave the decision as to the technical merit of differing bids to the proper person, namely, their engineer. Consequently, there is frequent accusation of graft in connection with the public letting of contracts. It is believed, however, that there is, at the present time, very little of the old-time "grafting" for the very good reason that a higher code of ethics obtains among both public officials and salesmen. Engineers in public office are showing a commendable courage in writing specifications so as to permit only those who manufacture suitable apparatus to bid. It is a weakness on the part of an engineer to write specifications so open that anybody and everybody can bid. It is a confession of his inability to specify.

The Sales Engineer Should Be Governed by a Sense of Public Duty

Furthermore, it is wrong to encourage a manufacturer to spend the time and money necessary to make up a bid when he has no chance whatever to benefit by it. Therefore, a salesman should urge engineers to limit the bidding to manufacturers of suitable apparatus even though by so doing he excludes his own company from bidding. Let him be prompted by as fine a sense of public duty as he can muster in matters that concern the American municipalities and frown down all attempts to misappropriate public funds.

Finally, let him bear in mind that the work that he is doing is a splendid work of education and that he is really doing pioneer service by educating able, wide-awake managers and engineers to practice better economies in natural resources, in labor and in time. Let him also uphold the dignity of his profession by giving fair and courteous treatment to others and by insisting upon fair and courteous treatment himself.

The remarkable effect of the buying of War-Savings Stamps has been the development of a finer sense of thrift and economy among the people.

Effect of Feed-Water Temperature and Rate of Injection Upon Steam Flow

By FRANK G. PHILO*

The author has plotted an interesting chart showing the effect on steam flow of the feed-water temperature and rate of feeding. Under any given condition the actual output of the boiler, expressed in B.t.u. absorbed per unit of time, is constant regardless of the rate of feeding and the temperature of the feed water.

INTERESTING data upon the changes of rate of steaming due to varying rates and temperatures of feed-water injection are shown upon consulting the steam tables and plotting results in graphical form shown by the chart accompanying this article. Under any given condition the actual output of the boiler expressed as B.t.u. absorbed per unit of time is constant, regardless of the rate and temperature at which the boiler feed water is injected. However, boiler output expressed in pounds of steam per unit of time varies widely with changing feed-water temperature and rate of feed-water injection, being highest when no water is being fed to the boiler and lowest when the feed-water temperature is very low and the water is injected at a high rate. When the feed water is fed into the boiler at the same rate at which the boiler is steaming, the normal condition will be considered to exist and the amount of water in the boiler will be constant. Any rate of feed-water injection above or below normal will increase or decrease the rate of boiler steaming and the amount of water in the boiler. Shutting off completely the supply of feed water will appreciably increase the rate of steam flow. On the other hand, any increase above the normal rate of feed-water injection will reduce the rate of steam flow; in fact, if the water is fed fast enough, steam flow will cease entirely. A still greater rate of injection will cause a reversal of steam flow from the line if the boiler is not equipped with nonreturn valves. If nonreturn valves are used, the pressure on the boiler being fed at this abnormally high rate will drop below line pressure. The aforementioned effects are most noticeable when very cold water is used and when the rate of steaming is low. An interesting example of the reverse effect of temperature of feed water is in cases where economizers are used and the temperature of the feed water is equal to or greater than, in some cases, the temperature of water in the boiler.[1] When the feed temperature is the same as the temperature of the feed water in the boiler, feed-water injection does not affect the rate of steaming. When the feed water is actually higher in temperature than that in the boiler, an increase in steam flow occurs upon feeding water into the boiler. The following formulas and the

accompanying chart and table will show the magnitude of the foregoing effects.

H = Total heat above feed-water temperature of one pound of steam;

L = Latent heat of one pound of steam under given conditions plus B.t.u. for superheating one pound of steam (if superheated):

h = Heat of feed water from feed temperature to boiler temperature;

R_s = Rate of steaming:

R_w = Rate of feed-water injection.

1. With feed water shut off entirely, $R_s = \frac{H}{L} = 1 \quad \frac{h}{L}$.

2. The rate of feed-water injection that would decrease steam flow to the rate R_s would be $R_w = 1 + \frac{L - R_sL}{h}$.

3. The rate of feed-water injection that would cause steam flow to cease, $R_w = 1 \quad \frac{L}{h}$. ($R_s$ = *zero.*)

4. Under any given condition the sum of the heat absorbed by the feed water and the heat used in boiling the water equals the total heat, or H absorbed by the boiler. As a formula this would be written $R_s L + R_w h = H$.

For examples of the foregoing take the conditions of 100 lb. gage, saturated steam, and 60 deg. F. feed-water temperature. Then $H = 1189 - (60 - 32) = 1161$ B.t.u.; $L = 880$ B.t.u.; and $h = 281$ B.t.u.

1. $R_s = \frac{H}{L} = \frac{1161}{880} = 1.32$, the rate of steaming with no feed.

2. Let $R_s = 50$ per cent., then $R_w = 1 + \frac{L - R_sL}{h} = 1 + \frac{880 - (0.5 \quad 880)}{281} = 2.57$, the rate of feed required to reduce the rate of steam flow to 50 per cent. of normal.

3. $R_w = 1 + \frac{L}{h} = 1 + \frac{880}{281} = 4.13$, the rate of feed required to stop steam flow.

As shown by the table and chart, variable feed-water injection with a steady load is disastrous to uniform steam pressure. Variable steam pressure, in turn, causes juggling of fires and short periods of loafing with consequent loss in efficiency of boilers and auxiliaries. However, with loads that have a periodic fluctuation, as in rolling mills, variable feed-water injection, if properly handled, aids the maintenance of the steam pressure. When the load is high the feed is decreased, and as the load drops the feed is increased, utilizing the heat absorbed by the boiler and admitting of fairly constant furnace conditions. This condenser action or heat-storage effect of the feed water is quite appreciable and is taken advantage of by intelligent water tenders. The matter of correct boiler feeding in the majority of cases is not given the attention it deserves, as the results of improved methods of boiler feeding are felt in the operation of the whole station as well as in the size of the coal pile.

The Fuel Administration points out the serious fuel shortage; careful feeding of water to boilers has its share in making up for this shortage of 80 million tons.

Reminiscences of a Boiler Inspector

By R. E. McNamara

While on the road making boiler inspections in the usual way, I once mailed a form card to a certain boiler user, giving notice of my intended visit, and designating the boilers I desired prepared for internal inspection on a certain date, about seven days later. I named a legal holiday and took special pains to see that nothing should interfere with my plans.

Arriving in the village in the evening I called up the superintendent of the plant and asked him if he had received my card and if the boilers would be ready, also if the plant would be running next day. He said that the plant would be running next day as usual notwithstanding the holiday, that the boilers were hot and could not be spared, that he had received my card, but that no arrangements could be made for inspection at that time. I therefore decided to make an external inspection only, so I walked out to the plant next morning, giving myself just about time enough to make an external inspection and catch the morning train. Passing the office of plant on the way, I dropped in. The superintendent was in, and I recalled the telephone conversation of the previous evening, remarking that as it was then only about 7 o'clock perhaps the engineer was not yet at the plant, but was told that the engineer was there and that there would be no trouble in getting in. Arriving at the plant imagine my surprise at finding that the group of boilers I especially desired to inspect were not only not hot, but had been idle for two months. The plant was not running, and there was not a man excepting the watchman to be on the premises that holiday. I routed the engineer out by telephone, and after his arrival he informed me that if he had known of my visit, the two remaining boilers could have been cooled off for inspection as well as not, for they were simply kept warm for emergency.

It is hard to imagine a superintendent, in daily and actual contact with a plant, not knowing more of the details than that. My first and very strong thought was that he had deliberately ignored my card and wilfully misled me in his statements, for it does not seem reasonable that any sensible and intelligent man could or would try to give plausible excuses for apparent contradictions of this kind. From what I afterward learned, however, I am convinced that he was honest in his statements and that it was a peculiar combination of circumstances that need not now be entered into that caused him to tell me what were in reality misstatements and grossly erroneous answers to my questions. Marvelous is the product known as human nature.

At another time, I recall, the date for the internal inspection of a plant had been set for a certain Sunday; that is, we had mailed the owner a card giving that date, for we knew that Sunday was the regular washout day. Arriving at the plant (which was about four miles from the regular path of travel, requiring a livery rig to reach it), I found the place locked up, with high brick walls all round and no apparent mode of entrance. Scouting around the neighborhood, which was new to me, no information concerning the superintendent or engineer could be had. Returning and walking around the premises again, I noticed that the cleanout door of the combustion chamber opened directly to the commons or field and that the combustion chamber had been cleaned that morning or at least very recently.

Not wishing to lose the time and trip, I made a change of clothes in the buggy, opened the combustion-chamber door and took the risk of being able to crawl over the grates into the boiler room. Fortunately, no trouble was experienced and entrance to the engine and boiler room was easy. The top manhole was open and a ¾-in. hose was pouring city water into the boiler which, from the appearance of the floor, had been washed that morning, and judging from the small amount of water in the boiler the cleaners had just left. I drained the boiler, made the inspection and thought to myself what a joke it would be on the management when they discovered what I had accomplished and how. I replaced the hose, turned on the water, crawled out, cleaned up the best I could and returned to the city.

I suppose my readers expect me to relate how I chalked my name on the inside of the boiler as proof or left my card in a conspicuous place to indicate my visit. I regret that this oversight came very near leading to serious complications, for it transpired that the management had not received the notification card and when the internal report reached them, they referred back to the date and at once notified the company that it was impossible for an inspection to have been made for the plant and boiler house were locked up and although it was true that the boiler had been washed on that date, the engineering force had seen nothing of the inspector. My company at once referred the matter to me, and I then saw what a mistake I had made, for it was not at all likely that, ordinarily, one would have used the method and made the inspection as I did, and it was equally as improbable that anyone else could be made to believe that I had resorted to this expedient. I suggested in my letter containing a full statement of the case that the livery-stable driver might add his testimony if asked. I never heard more of the incident other than a warning from my company which at least indicated a doubt on their part. Since then, whenever I find myself in a plant alone or without witnesses when an inspection is made, as a precautionary measure I post my card as proof of my presence. I doubt very much, however, if I will ever again make such a back-door entrance to make a boiler inspection.

Heating System Returns Connected Wrong

By T. W. Reynolds

Connecting heating-system returns as shown in Fig. 1 caused considerable difficulty in a certain large railroad station. There was a 6-in. return from the station proper and a 4-in. return from the express company annex, the 6-in. main running under ground all the way around the building to drain the various radiators. Its elevation was somewhat above the receiving tank except for the portion that ran along the boiler-room floor to connect with the receiving tank. Radiation in the annex is overhead, and the 4-in. return from these coils is also overhead and at a considerably greater elevation than the 6-in. return to which it is connected at its lowest point near the receiving tank as shown in Fig. 1. The boiler-feed pumps take their suction from this tank, 3 ft. 6 in. in diameter and 5 ft. high. Any necessary makeup water is admitted to the tank by means of an automatic feeder. Steam is circulated throughout the heating systems without interference; that is, there are no steam traps or automatic valves on the returns and there is therefore practically the same pressure in the return as in the supply.

The annex is a narrow, low building about 500 ft. long, the front of which is practically all doors, so that during the rush hours from 4 to 6, morning and afternoon, these doors are all opened and the heating requirements are greatly increased. Because of this demand for steam the pressure is lowered, consequently the condensate does not flow back freely when retarded by the higher pressure within the station return. This resulted in flooded radiators with hot water as a heating medium rather than steam and at a rapidly decreasing temperature. Therefore, when most needed, the heating system failed to heat the annex. Furthermore, the flooding extended to the lower portion of the station return until the static head in the 4-in. return balanced the greater steam pressure in the 6-in. main. Later, the flow of condensate surging back to the tank would cause it to overflow and waste through a pipe leading to a sump. This sump contained a cellar drainer of insufficient size for such large quantities of water, so that the boiler-room floor was soon flooded.

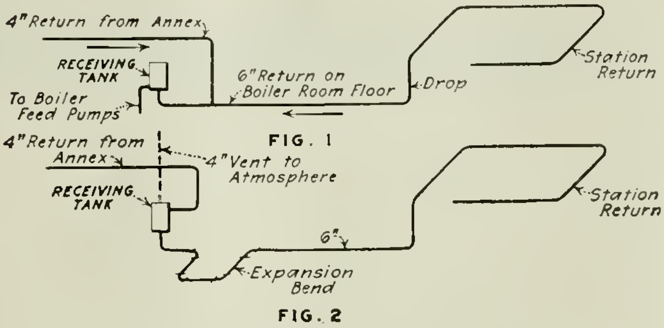

FIG. 1

FIG. 2

FIGS. 1 AND 2. CHANGES IN RETURNS FROM TWO BUILDINGS

Fig. 1—Returns join before entering receiving tank. Fig. 2—Return lines connected to tank separately

Under such conditions the colder water from the annex mingling with the hotter water from the station created extreme water-hammer, sometimes extending to remote points within the building, and the movement of the 6-in. return caused a considerable stress. The water-hammer was greatest at the receiving tank and was of such force as to cause alarm; the brick foundation under the tank cracked and spread; fittings and joints leaked or were cracked, requiring frequent renewals.

The remedy was simple and was made as shown in Fig. 2. An expansion loop of four ells was placed in the 6-in. return; the brick foundation under the receiving tank was replaced with iron-pipe standards flanged to the floor and tank. The two returns were connected separately into the tank, the one from the annex near the top, the other, as before, at the bottom. A 4-in. vent was run from the tank to the atmosphere, relieving the back pressure that slowed up the returns and the water-hammer was eliminated.

The Vanishing Factor

THE average steam boiler under pressure possesses about as much potential power for destructiveness as a healthy deep-sea mine in the heyday of its existence, and frequently it lets loose all its energy on apparently smaller provocation than would disturb a mine of normal temperament and placid disposition. To offset this tendency toward unexpected and undesirable scatteration, we have adopted the plan of building our boilers with what we call a factor of safety—otherwise known as a factor of ignorance.

Under the circumstances, this procedure is the best that can be devised. We are not absolutely sure that every inch of the steel we use in the construction of the shell has the same characteristics as the test piece. We are not at all certain that the pressure for which the vessel is designed will not be exceeded considerably. Our knowledge of the stresses induced in the shell material by the methods of construction and the heat of the furnace is not so exact as we could wish. So we wrap up all our uncertainties into one package, label it "factor of safety," make everything five or six times as strong as the maximum shown by our calculations and trust that we have made the ante sufficiently high to forestall annoying consequences.

Too often our childlike confidence is shamefully betrayed. But when the coroner has completed his investigation and we have managed to collect the widely distributed pieces of boiler and examine them, we are usually a little better informed as to what causes boiler explosions.

Of course, we know at the outset that the sole cause of boiler explosions is the disappearance of the factor of safety, leaving no margin between the load on the shell and the power of resistance. The great trouble is that we are not yet clever enough to catch it in the vanishing act in all cases. Careful periodic inspection frequently detects it gumshoeing into oblivion, but it still has a tantilizing way of taking French leave.

However, we are considerably wiser than we used to be, for we know to some extent why and where the disappearance occurs. Plenty of explosions have their beginning in cracks along riveted seams. We have discovered, through careful and methodical tests, that when a strip of metal having a transverse hole in it is subjected to tension in the direction of its length, the tensile stress at the edges of the hole may be two or three times as great as the average tensile stress in the full cross-section of the strip.

The drilled plates of a riveted joint are similar to the test bar just mentioned, and we are led to suspect that the cracks which develop into disastrous failures have their beginning in minute fractures along the edges of the rivet holes, due to excessive stresses at these points. If we admit that these extraordinary stresses are perhaps twice as great as that considered in our average calculations, we say farewell to half of our adopted factor of safety on the instant.

In a boiler there is a breathing action due to the change of pressure with the periodic drafts of the engines or changing conditions of service, resulting in what are called repeated stresses. The shell is thus subjected to a series of changes of load, varying between fairly wide limits, and we know from the results of tests on iron and steel that a specimen subjected to a considerable number of alternately varying stresses, even though all of them are within the elastic limit, will eventually fail at a stress having a value of only half or two-thirds the normal strength. Therefore, under the long-continued increase and decrease of pressure of a boiler, a point may be reached where the resistance of the material is reduced to half of what might ordinarily be expected of it, and immediately another considerable fraction of our factor of safety evaporates into thin air.

We have made the discovery that caustic soda has an embrittling effect on mild steel such as is used in boiler construction, this action resulting apparently from the occlusion of hydrogen in the metal. Caustic soda forms a very common agent for the treatment of feed water, and if it is present in the boiler we may expect it to have some effect on the steel under favorable conditions. This embrittling renders the metal less able to withstand the loads put upon it. And so our factor of safety takes a further decline.

Considering these points—and they are far from being a complete catalog of the influences affecting the strength of a steam boiler—we begin to appreciate the reason for the reduction of the factor of safety. The unfortunate part of the whole matter is that we have had to obtain so much of our knowledge of the causes of explosions from costly experience; but, after all, that is exactly how the world has accumulated most of the facts it now possesses.

Camouflaged by Coal Conservation

EVERY good American will applaud the untiring efforts of the United States Fuel Administration to conserve the coal supply, even though the means suggested for the attainment of this end may put him to inconvenience and expense. He realizes that by subordinating his own likes and dislikes he is patriotically doing his share to further the common cause.

On the contrary, he is entitled to voice his disapproval and make an emphatic protest when he sees a ruling of the Fuel Administration made an instrument for building up one group of interests at the expense of another, in violation of all the laws of fair play and with little or no regard for the spirit of the ruling.

Charles E. Stuart, chief of the Power and Light Division of the Fuel Administration, has announced a series of plans for the saving of coal, foremost among which is placed the elimination of uneconomical isolated plants. Elaborating on this particular topic, Mr. Stuart says:

> The individualistic way in which fuel is now consumed in cities is not efficient. A ton of coal burned in a large central station will produce at least four times as much electric power as if burned in the average small plant, and if centralized burning could be introduced to a greater extent, the amount of fuel required could be reduced without reducing in any way the ultimate production of light and power.

No one denies that the central station is able to produce a kilowatt-hour with a smaller expenditure of coal than the small plant; but that is far from being the whole of the story. Electrical power is only one of the products of the heat energy in coal. There is a trinity of such products—heat, light and power—and all three are essential to human comfort and industrial existence.

If the people of this country were like a race of moon-dwellers, capable of enduring the rigors of winter without discomfort, then there might be a general shutting down of isolated plants. But so long as heating is required, just so long will the isolated plant for combined heating and electric generation have undisputed sway in a field in which the central station, with all its vaunted efficiency, cannot successfully compete.

Continuing, Mr. Stuart says:

> It is sometimes the case that in buildings where there are electric plants and where exhaust steam is utilized in the heating of the building and in furnishing hot-water requirements, central-station service can be adopted without a loss of money and at a saving in fuel.

This statement is diametrically opposed to all the results of experience in isolated plants using exhaust steam for heating. It is so completely at variance with the facts that it denotes either astounding ignorance of the subject or a deliberate attempt to distort the truth. In either case it stamps its author as an inaccurate spokesman for a Governmental department whose avowed purpose is to deal intelligently with the coal-conservation problem.

The Fuel Administration has repeatedly stated its intention to impose a minimum of hardship in enforcing fuel conservation. The wholesale shutting down of isolated plants and the compulsory substitution of central-station service would not only be a gross repudiation of that policy, but it would be a national disaster.

The oft-repeated assertion as to the splendid efficiency of the central station resulted in a passive acceptance of the statement. The popular mind became largely obsessed with the belief, just as it took for granted the much-heralded efficiency of the German. But, just as Teutonic efficiency has been shown to be a ridiculously overrated quality—in some cases even a negative quantity—so the preëminence of the central station has been found to exist largely as a state of mind rather than as an engineering fact.

The truth of the matter is that central-station service increases the coal consumption and the expense in any plant that has use for exhaust steam. From the viewpoint of coal conservation, the universal adoption of central-station service would be a huge and costly joke, and the country is in no mood for that sort of diversion at the present time.

The Fuel Administration, probably unwittingly, is in danger of being used by the overzealous henchmen of the central station as a bludgeon to beat the isolated plant into a condition of permanent coma. The isolated plant is painfully aware of its economic weaknesses. It is equally aware of its strong points, and it is well fortified with facts to meet the open onslaught of the central station. But it is at a decided disadvantage in a conflict in which its adversary skulkingly takes refuge behind the bulwark of the Fuel Administration and snipes away like a boche sharpshooter ensconced behind a crucifix.

Those Devil-Hounds

THE hearts of all unhyphenated Americans have been thrilled on reading the accounts of the splendid showing made by our troops in France under the conditions of open warfare brought about by the recent German offensives. It is a style of fighting to which they are adapted by both training and temperament. It makes the conflict a contest of individual skill and courage, in which the American soldier asks no odds of any adversary.

The dash, the intrepidity, the disregard of danger and punishment displayed by the marines in their engagements on the western front heartened and cheered the battle-weary troops of our Allies and electrified the spirits of our people at home. The effect went even farther than that. It taught the boche a wholesome respect for the new fighting element, which the German high command had hitherto affected to regard with sneering contempt; it proved, even to the wilfully blind and thickheaded Teutons, that the forces arriving by the hundreds of thousands from the western world constitute a factor that must be taken into account in the final reckoning; and it earned for those fearless fighters the German appellation of "devil-hounds."

The epithet thus applied becomes a title of merit when interpreted as shown by the artist in the colored supplement to this issue. The marines are hounding and harrying the German beast, and its snarls of rage and hate indicate all too plainly that it has felt the fangs of its tormentor.

It is this beast—the incarnation of all things unspeakable and devilish, glutted with conquest and lusting for further outrages—that stands as a hideous menace to the freedom and happiness of the peoples of the world. For the safety of the generations yet unborn it must be cowed, driven back, overwhelmed and slain. Our marines have splendidly begun the mighty task. Our swiftly arming millions will gloriously finish it.

In history there is one example of physical force, of military might, becoming so strong that nothing but force could overcome it. The Roman Empire reached that stage. It was not conquered; it died of rot; it wrecked itself in the decay of the Middle Ages. The works of civilization of the past were stamped under the oppressor's foot and the world relapsed into barbarism and darkness that lasted during the centuries of the Dark Ages. The world now faces a similar situation; and to prevent it, the military might of Germany must be crushed; otherwise it will die by slow rot, ever so much slower than the Roman Empire because of the science and technique of the oppressor.—*P. B. Noyes, Director Conservation Division, United States Fuel Administration, at annual dinner of the National Electric Light Association, Atlantic City.*

Using a Pitot Tube

Referring to the articles on pitot tubes on page 195, Feb. 5, and page 520, Apr. 9, there are graphic methods often useful for reducing the data to the average velocity head. One method that shows directly the locations in the cross-section of the pipe where it is desirable to take readings near together, for the sake of accuracy, and that gives each observation its proper influence on the result, may be explained as follows:

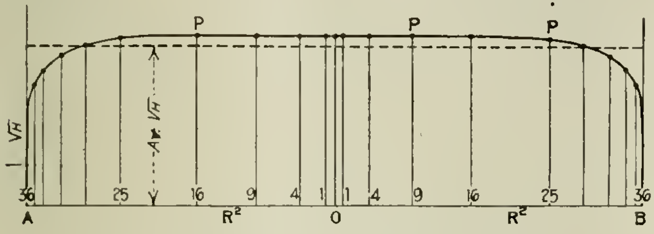

CHART SHOWING AREAS PROPORTIONAL TO FLOW IN PIPES

Since the volume passing a given section is the product of the area of the section and the velocity, these factors being πR^2 and $\sqrt{2gH}$, a plot laid out with values of R^2 and $\sqrt{H}$ as coördinates gives an area that is proportional to the flow. In the illustration, representing a flow of air, *O* represents the center of the pipe and readings *H* are taken by the pitot tube at known distances *R* away from the center across the diameter. Then each reading gives a point *P* located by laying out the distance R^2 from *O* along the base-line, and erecting $\sqrt{H}$ as an ordinate. The distance $OA = OB$ is the square of the radius of the pipe. The closed figure formed by the line joining points *P* and the base-line has an area proportional to the flow, and the average $\sqrt{H}$ is found by dividing this area, as found by planimeter, by the length *AB*.

The method is somewhat longer than the one in which the average pressure is found from concentric rings of equal area, but additional points are more readily represented. C. H. CHASE.

Stoneham, Mass.

Charged Steam Pipe

H. S. Whitney's letter, "An Electrical Phenomenon," published in *Power*, Feb. 12, and Dr. K. Becker's comments on this letter, in the issue of Apr. 23, bring to mind a somewhat similar experience with static electricity caused by a steam leak.

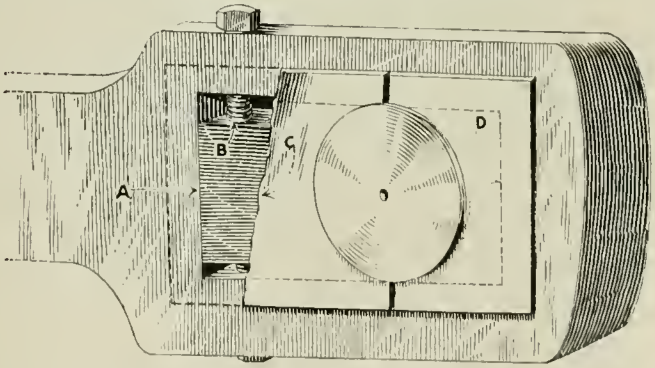
In a plant in which I was working it became necessary to install a supporting strap on one of the steam pipes. A steam fitter went up on a ladder to do the job, but on touching the pipe with a tool, he received a shock that almost knocked him down. As a temporary measure of relief a copper wire was connected between the charged-pipe section and a water main, so that the electric pressure could not accumulate as a charge. Later, a careful inspection was made for a contact between some live wire and a pipe or iron part of the building, but no such contact could be found.

The cause of the charged condition was not discovered until a week or ten days later, when a steam leak in the affected section was stopped; after repairing the leak, the charged condition no longer existed. The blowing of steam through the leak generated the electricity, which, ordinarily, could not have accumulated as a charge, because in most cases it would have followed the pipe line to ground. In this case, however, the pipe line had been installed a long time, and the joints on both sides of the affected section acted as insulation by virtue of rust and the intervening rubber gaskets between the flanges. E. C. PARHAM.

Brooklyn, N. Y.

Engine Broke Wedge Bolts

The crosshead ends of the connecting-rods of some of our engines are designed as shown in the illustration, and when all the adjustment was taken up on one of the engines, I raised the wedge, and as there was a thin shim at *A*, I thoughtlessly inserted another in the same place. The engine ran only a few hours before one of the wedge bolts broke off at *B* close to the adjusting wedge. I put in a new bolt, but the engine broke two more bolts at the same place in less than a week. I then decided it was time to use my head a little and reasoned that the shims being inserted at *A* threw the threaded hole in the wedge out of line with the hole through the strap, causing undue strain on the bolts, which broke them. I took the shims out and put them in at *C*, and the engine has never broken another bolt.



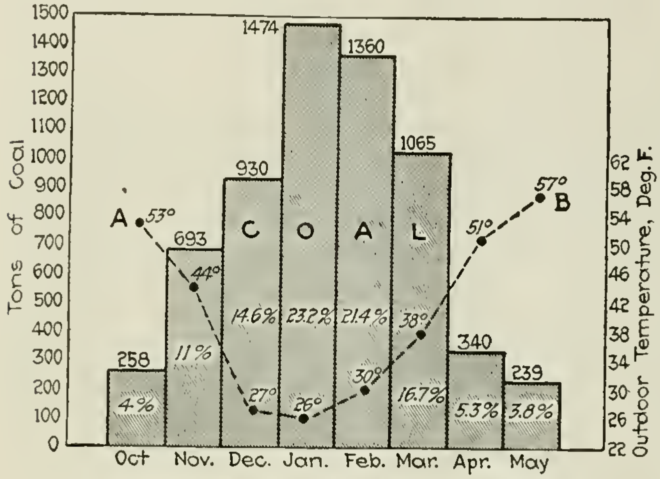
LINERS PUT IN THE WRONG PLACE

Whether the shim should be put at *C* or at *D* depends on the travel clearance of the piston. A shim at *C* will lengthen the rod and reduce the clearance at the head end of the cylinder, while the reverse will be true if the shim is put in at *D*. W. G. CAMP.

Ash Fork, Ariz.

Coal for Live-Steam Heating Plant

The amount of coal required for heating and the percentage of the total for the season used each month are valuable data in these days of coal shortage and lack of transportation facilities. In this connection the article by M. W. Ehrlich, on "Average and Maximum Heating Demand," in the Mar. 5 issue of POWER is interesting. In many large buildings the power and heating are combined, and with a scarcity of meters of the proper character it is difficult to separate the coal for the different services. Data from a live-steam heating plant, where coal is burned for heating only, may be of interest. Averages covering the three years, 1915, 1916 and 1917, for the retail department store of Marshall Field & Co. are presented herewith. The data apply to the main building, which is 380 ft. long, 380 ft. wide and 270 ft. high, giving in round numbers an interior volume to be heated of 39,000,000 cu.ft. Illinois washed nut coal averaging 12,000 B.t.u. per lb. is burned.



COAL USED PER MONTH IN TONS AND PERCENTAGE

Extending from October into May the heating season averaged 200 days of 14 hours, or a total of 2800 hours. The average coal consumption was 6359 tons per season. Above the first-floor line the building contains 215,000 sq.ft. of direct radiation, and the cubical content is 32,500,000 cu.ft. This space is 83 per cent. of the total and requires 90 per cent. of the coal, or 11,446,200 lb. Thus the coal consumption per season for that part of the building above ground reduces to 53.2 lb. per sq.ft. of direct radiation. Per 1000 cu.ft. of building space the coal consumption for the season reduces to 352 lb., and this in the writer's opinion is the better ratio to use in comparing the heating requirements of various buildings.

The chart shows the tons of coal used each month, including October and May, and in each case the percentage of the total for the season is given. These figures include the coal required to heat the basements and are given to show the relative quantities of coal required in the different months of the season. The basement has 15,000 sq.ft. of indirect surface, which is usually conceded to be equivalent to about 45,000 sq.ft. of direct radiation. The dotted curve gives the average of outdoor temperature readings taken at 8 a. m. and 4 p. m. every day of the heating season.

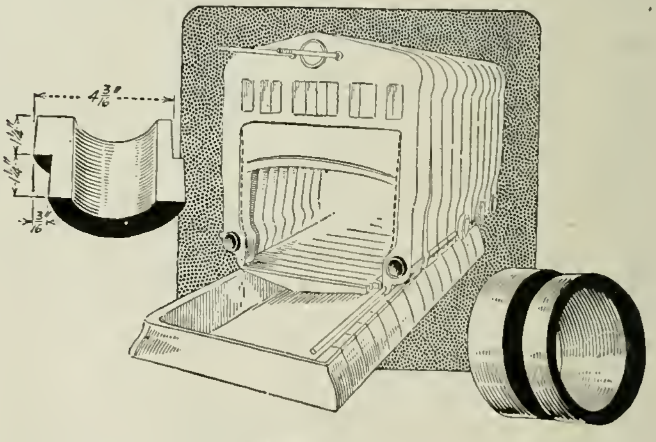
Chicago, Ill. C. W. NAYLOR.

Fitting New Sections to a Warped Boiler

In the layout of the heating system of a church in Tarrytown, N. Y., one boiler of nine sections was installed to heat both the parish house, which must be continually heated, and the church, which is heated only on Sundays. The furnace is in the basement of the parish house, and to heat the house and not the church all that is necessary is to have a low fire, not hot enough to force steam over to the church but enough for the house. No valves were provided to shut off the steam from the church. This works fairly well, but there is one trouble; when the church is not heated, there is no way to drain the returns and they remain full of water and are in danger of freezing. In fact one of them did freeze and burst during a cold spell last winter. The sexton built a hot fire under the boiler, got a steam pressure of .15 lb. about 6 p.m. Saturday and then left the church without discovering the burst pipe. He returned at 10:30 that evening and found that all the water had been driven out from the boiler. With the very hot fire and no water in the boiler, the front section was warped out of line one-half inch; resulting in damage amounting to $400. When the new sections arrived, the front section fitted nicely, but the last old section was warped out of line one-half inch; in fact, at least four and probably five sections were warped or spread at the bottom, as shown in the illustration; and being cast iron, it was impossible to force them into place.

Experts were called in, and each one maintained that it would be impossible to fix them so they could be used and that new sections would be necessary at a further cost of $500 to $600. It seemed to me that there must be some way to use these sections, which were still good, having stood a cold-water test of 10 lb. Careful measurements were than made to determine how much the nipple holes were out of alignment and it was found that the difference was $\frac{3}{16}$ in. on one side and $\frac{5}{16}$ on the other. Two eccentric, or offset, nipples were made accordingly, with slightly more taper than the regular nipples, and with these the new section of the boiler slipped into place with the same ease as in regular construction. A tight joint was made, and the boiler is giving satisfaction. The saving was nearly $600. As far as I can find out, this is the first time such a repair has been tried out. D. C. ASHMEAD.

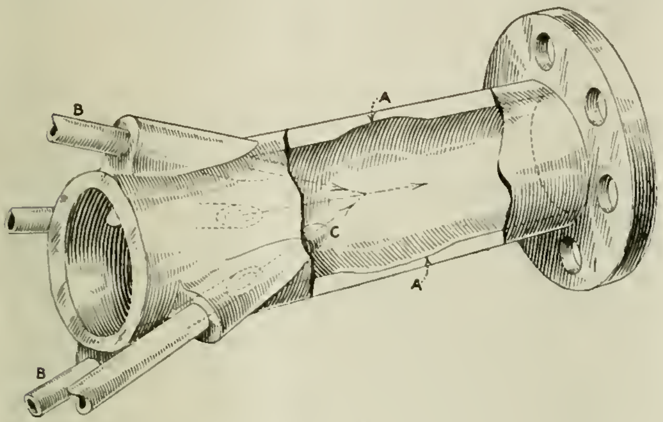
Tarrytown, N. Y.



OFFSET NIPPLES COMPENSATE FOR MISALIGNMENT

Suggested Steam-Jet Ash-Conveyor Improvements

The operation of steam-jet ash conveyors is simple and so is their construction in the main, but my experience with them indicates that there are one or two parts that might be improved. One is in relation to the method of placing the steam nozzles in the nozzle section. In the system I am using, there are two jets placed diametrically opposite and at an angle of about 15 to 20 deg. with the axis of the pipe. The streams issuing from these nozzles come together at a point depending upon the size of the pipe and upon the angle of the nozzles.



PROPOSED ARRANGEMENT OF STEAM JETS

The indications are that the jets coming together as they do, tend to combine and form a jet similar to that of the gas flame. This shape of jet, together with the ashes, causes a scouring action at the top and bottom of the pipe, as shown in the sketch at *AA*. This pipe is 8 in. diameter, 1 in. thick and 8 ft. long and is of chilled cast iron, which makes frequent renewals expensive. The best way, I believe, is to correct the trouble at the nozzles by placing them so that the resultant discharge is a cone-shaped stream. I believe that this could be done by adding two other nozzles placed as shown at *BB*, or 90 deg. from the present nozzles, which would tend to prevent this action. Care must be taken to have the center line of the nozzles lie in the same plane with the axis of the pipe, or a spiral or centrifugal scouring will be caused. With the coming of warm weather I expect to change the nozzles I am operating, as suggested herein.

The second improvement relates to sharp 90-deg. bends, which, from the point of economy in steam consumption and upkeep, should be replaced with long-radius bends fitted with cast-iron baffle plates. The long bends should be made sectional, as some of them are, so as to be easily replaced.

We have recently installed a skip hoist and tank ash-handling system, and as soon as possible I will forward data giving a comparison of the operation of both systems. Although the jet type of conveyor uses a greater amount of steam during the time it is engaged in removing ashes, the steam is used but a short time at each ash removal, and the system has the advantage of being capable of taking care of a great overload, which cannot be said of the skip hoist unless it is of very liberal size. **H. G. Burrill.**

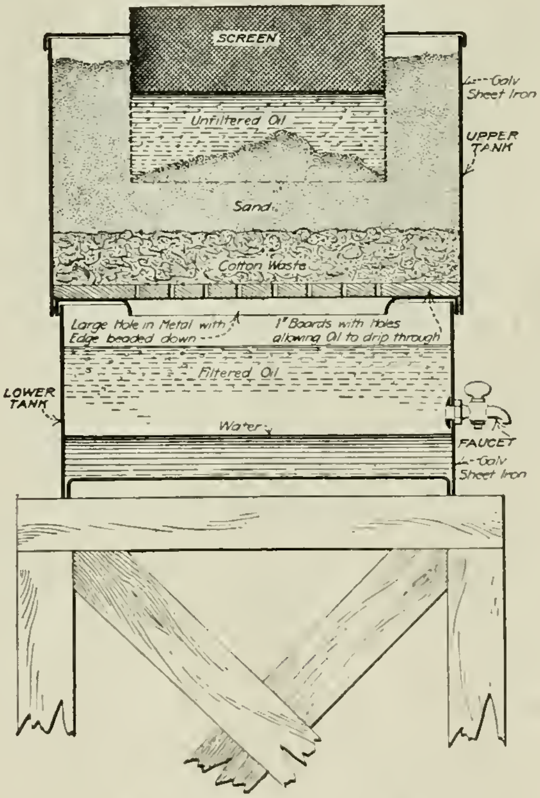
Herkimer, N. Y.

Sand Filter for Used Oil

Perhaps other power-plant engineers have experienced difficulty in filtering lubricating oils which have become heavily laden with grit and other foreign substance. The illustration shows a primary filter, which I constructed, to take care of black and badly carbonized lubricating oil drawn from the well of a semi-Diesel fuel-oil engine, which has proved entirely satisfactory for the purpose. I found that, quite contrary to the prevailing opinion, oil can be filtered through sand without danger of injury to the most delicate bearings in which it may be used later. After the oil is drawn from this filter it is, as an extra precaution, put through a standard make of oil filter.

The upper tank can be removed from the lower tank or reservoir for cleaning. The water in the lower tank is not necessary, but since a space for settling is left below the faucet, the use of water obviates the necessity for the excessive amount of oil which would otherwise be required to bring it to the faucet level. The construction of the upper tank is such that it will fit nicely on the lower tank and prevent the oil from creeping to the outer edges by the bottom having a large hole cut in the center and its edges beaded down, as shown.

The plan of screen arrangement allows for the adjustment of the amount of sand through which the oil must pass before reaching the waste, and by bringing the sand up around the sides of the screen, the oil is prevented from seeping down between the side of the tank and the sand unfiltered.



SAND USED IN FIRST STAGE OF FILTER

I will appreciate comments in the columns of *Power* and suggestions for improvements and also to know whether any engineer has previously used such a filter.

Harvard, Neb. **Julius E. Person.**

Supporting Effect of Boiler Heads

I was much interested in the article by Neil M. Macdonald in *Power* of May 21, wherein it is shown that the strength of the unsupported head should not be added to the strength of the stays to find the allowable pressure in a boiler. However, I question Mr. Macdonald's line of reasoning.

Let us confine our argument to the very good illustration of the two walls joined by a rope. The author states that "when the pressure reaches 528 lb., which is the ultimate strength of the rope, the rope breaks." This is not so, for the weaker wall is able to withstand 296 lb., so that there is a pull on the rope of only 232 lb., and the rope will not break. The author admits that "the pressure rises slowly until 296 lb. is reached . . . but there is no perceptible change in conditions, as both walls still stand and the rope is still intact." In other words, the rope is not subjected to any stress as long as the pressure on the wall is less than 296 lb., so that when the pressure on the wall is greater than 296 lb., the pull on the rope is equal to the amount that the pressure exceeds 296 lb. The pull on the rope will equal 528 lb. only when the pressure on the wall has reached 824 lb. Hence, the strength of the unsupported head should be added to the strength of the stays to obtain the allowable pressure in a boiler.

Bridgeport, Conn. D. Fliegelman.

A hasty first perusal of the article in the May 21 issue of *Power*, page 733, caused the writer to wonder if the author of that article was serious in his views or merely wanted to start something. If Mr. Macdonald's argument is a valid one, then in every line of machine design much material has been added uselessly in order to give supposedly greater strength to some weak member.

It seems strange that he did not go a step farther and assume that sixteen braces supported the head. He should have assumed that the total load to be carried by these sixteen stays was 80,000 lb. so that each stay would singly support 5000 lb. Then, using his "wall" argument, when the load rose to 5500 lb. one stay would break, since this was beyond its capacity; then the second, third, etc., would successively break under this load.

The conclusion to be drawn would follow the conclusion he stated—the strength of the boiler or stone wall was the strength of its strongest part, namely, one stay or brace. Absurd, you will promptly decide. No more than Mr. Macdonald's conclusion. Why does he not state the actual conditions existing in his wall? If he loads it with 528 lb., it can be assumed either that the rope bears all the pressure or that it is divided between the wall and the rope. Now, the wall has a resistance of 296 lb., then surely 296 lb. can be added before the combined resistance is overcome.

Philadelphia, Penn. E. S. Morrison.

The article in the May 21 issue of *Power*, page 733, seems correct to me in its final conclusion, namely, that a boiler head should be stayed without taking into account the strength of the unstayed head. But is the author not mistaken in his explanation of the reason why? It looks to me that with his weaker and stronger wall with a rope between, the strength of the weaker wall can safely be added to the strength of the rope to find the pressure at which the rope will break and the wall topple over, for both are rigid and both give their ultimate strength in the same position and at the same time. But with the boiler head it is not the same, for while the head might be ultimately strong enough to withstand considerable pressure, the pressure it will stand and remain in position is very much less; therefore, the stays must take the whole pressure, for the position the head will take under little pressure is beyond the position where stays will be broken off.

To illustrate, take a spiral spring with an eye-bolt in each end, hook up one end and hang a weight on the other end. Suppose that the spring will sustain a weight of 1000 lb. Now take the weight off, put a solid bolt from eye-bolt to eye-bolt through the center of the spring, make it just the right length so that the spring will be in its normal unstrained position, and make the bolt of sufficient strength to support 2000 lb. It is possible that some might think that the combined bolt and spring would suspend 3000 lb., and they would but for the fact that the bolt will be broken before the spring begins to take any material part of the load.

A wall and a tight rope, two bolts or any other combination of materials that will take strain at the same time, up to their ultimate strength, will have the resistance of one plus the other. With the spring and bolt, or the stayed boiler head, the strain it will stand is the strength of the first to fetch up, plus whatever strain is on the other element in the position where the first member takes up, and no more. With the boiler so little pressure will cause the flat head to move away from the pressure, that in figuring the strength of stays to keep the head in place the effect of the head should not be reckoned and is not in practice, usually. L. Johnson.

Exeter, N. H.

Wood for Pipe Covering Dangerous

On page 742 in the issue of May 21 there is a description of a system of pipe covering, which is not new, and is not desirable, as it is dangerous. Back in the early 80's I was in charge of a plant in the Middle West, in which the steam piping was covered in a similar manner and I think it had been patented. Having to make some changes in the piping to the cylinder lubricator, which was connected into the steam pipe just above the throttle valve, I had to remove some of the pipe covering and found almost all of the wood converted to charcoal, so soft that it could be easily crushed to powder with the fingers, and a spark would have started a blaze. The old covering was therefore ripped off, and a covering more nearly fireproof substituted.

In "ye olden times" it was the custom also to lag engine cylinders with fancy wood, but wherever this lagging was in contact with the bare metal it would invariably char, and steam pressures were low then compared with present practice, one hundred pounds being considered high. Alonzo G. Collins.

Philadelphia, Penn.

Inquiries of General Interest

Over-All Efficiency of Pumping Plant—What would be the over-all efficiency, or ratio of water horsepower to electric input, of an electrically driven pumping plant, where the efficiency of the motor is 85 per cent., efficiency of pump 70 per cent. and efficiency of pipe lines 75 per cent.? J. H. N.

The over-all, or combined, efficiency would be the product of the separate efficiencies: namely, 0.85 × 0.70 × 0.75 = 0.44625, or practically 45 per cent.

Height of Barometric Condenser—Would there be any gain in vacuum by raising a barometric condenser from 34 ft. to 38 or 40 ft. above the water in the hotwell? L. B. R.

The purpose of having an elevated discharge pipe is to obtain a column of water that will produce sufficient pressure for the water to discharge itself against the pressure of the atmosphere acting on the water of the hotwell. Under ordinary conditions, 34 ft. is sufficient for the purpose, and additional height would be of no advantage.

I.Hp. for Increase of R.P.M. and M.E.P.—An engine running at 75 r.p.m. with 40 lb. m.e.p. develops 100 i.hp. If the speed is increased to 80 r.p.m., what number of horsepower would be developed with 45 lb. m.e.p.? J. J. H.

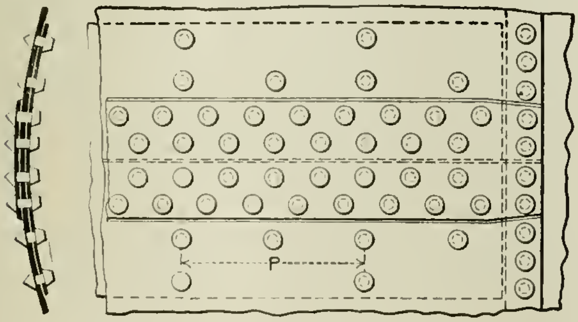
The power developed would be directly in proportion to the speed and the mean effective pressure. Therefore with 80 r.p.m. and 45 lb. m.e.p. the engine would develop

$$100 \times \frac{80}{75} \times \frac{45}{40} = 120 \text{ i.hp.}$$

Break in Boiler-Feed Line from Stoppage of Pump—My foreman states that stopping of the feed pump was the cause for frequent breaking of a tee in the feed line. How could that occur? M. S. C.

Stoppage of the pump might be an indirect cause of the breakage from expansion of the feed line, as a result of the feed line becoming heated from leakage of a boiler check valve; but breakage of the line from overheating should not happen if the feed line is laid out with proper allowances for expansion and contraction.

Efficiency of Quadruple-Riveted Boiler Joint—What is the efficiency of a quadruple-riveted butt and double-strap boiler joint like the sketch, made of steel plates of 55,000 T.S. and 95,000 lb. crushing strength, and having main plates ½ in. thick; butt straps $\frac{7}{16}$ in. thick; P, the pitch of rivets in the outer row, 14 in.; diameter of rivets after driving, $\frac{15}{16}$ in.; shearing strength of rivets in single shear, 44,000 lb., and in double shear 88,000 lb. per square inch? I. T.



The diameter of the rivet holes and rivets after driving would be $\frac{15}{16}$ = 0.9375 in., and each rivet would have a cross-sectional area of 0.9375 × 0.9375 × 0.7854 = 0.6903 sq.in. For each unit length of joint = P, there would be three rivets in single shear and eight rivets in double shear and for such unit of length there would be,

(A) Strength of solid plate,

14 × 0.5 × 55,000 = 385,000 *lb.*

The strength of the joint per unit P of length would depend on one of the following considerations:

(B) Strength of plate between rivet holes in the outer row,

(14 — 0.9375) 0.5 × 55,000 = 359,219 *lb.*

(C) Shearing strength of eight rivets in double shear, plus the shearing strength of three rivets in single shear,

(8 × 88,000 × 0.6903) + (3 × 44,000 × 0.6903) = 577,091 *lb.*

(D) Strength of plate between rivet holes in the second row, plus the shearing strength of one rivet in single shear in the outer row,

[[14 — (2 × 0.9375)] 0.5 × 55,000] + (1 × 44,000 × 0.6903) = 363,811 *lb.*

(E) Strength of plate between rivet holes in the third row, plus the shearing strength in single shear of two rivets in the second row and of one rivet in the outer row,

[[14 — (4 × 0.9375)] 0.5 × 55,000] + (3 × 44,000 × 0.6903) = 372,995 *lb.*

(F) Strength of plate between rivet holes in the second row, plus the crushing strength of butt strap in front of one rivet in the outer row,

[[14 — (2 × 0.9375)] 0.5 × 55,000] + (0.9375 × 0.4375 × 95,000) = 372,402 *lb.*

(G) Strength of plate between rivet holes in the third row, plus the crushing strength of butt strap in front of two rivets in the second row and one rivet in the outer row,

[[14 — (4 × 0.9375)] 0.5 × 55,000] + (3 × 0.9375 × 0.4375 × 95,000) = 398,770 *lb.*

(H) Crushing strength of plate in front of eight rivets, plus the crushing strength of butt strap in front of three rivets,

(8 × 0.9375 × 0.5 × 95,000) + (3 × 0.9375 × 0.4375 × 95,000) = 473,145 *lb.*

(I) Crushing strength of plate in front of eight rivets, plus the shearing strength, in single shear, of two rivets in the second row and one rivet in the outer row,

(8 × 0.9375 × 0.5 × 95,000) + (3 × 44,000 × 0.6903) = 447,370 *lb.*

There would be least strength of the joint from consideration (B) and the efficiency of the joint would be

$$\frac{(B)}{(A)} = \frac{359{,}219}{385{,}000} = 93.3 \textit{ per cent.}$$

Power Absorbed by Idler Pulley—How much power is lost from the use of a 28-in. diameter idler pulley on a 2½-in. shaft making 220 r.p.m., used to hold a quarter-turn of a 17-in. double leather belt? A. T. M.

The power lost by use of the idler consists mainly of the bearing friction that results from pressure resulting from the direction and tension of the belt and the weight of the belt, pulley and shaft. The maximum belt tension probably would not exceed 90 lb. per inch of belt width, or about 17 × 90 = 1530 lb., and having a belt angle of 90 deg. the resulting pressure from belt tension would be 1530 × 1.4 = 2142 lb. The horsepower absorbed by friction of shafting, with continuously oiled bearings, is approximately equal to

Total pressure in bearings in pounds × diameter of bearings in inches × r.p.m. ÷ 2,900,000.

Allowing the total pressure on the bearings from belt tension and weight of belt, pulley and shaft to be 2500 lb., the power lost by friction would be 2500 lb. × 2.5 in. diameter × 220 r.p.m. ÷ 2,900,000 = 0.47 or about one-half horsepower.

[Correspondents sending in inquiries should sign their communications with full names and post office addresses. This is necessary to guarantee the good faith of the communications and for the inquiries to receive attention.—Editor.]

Meeting of National Electric Light Association at Atlantic City

THE thirty-fourth annual meeting of the National Electric Light Association was held in the Hotel Traymore, Atlantic City, N. J., June 13 and 14. In the words of W. W. Freeman, past president of the association, it was "The most serious and the most inspiring convention the association ever held." The attendance was comparatively small, only a little over 300 being registered, owing to many being away on and too busy to leave war work.

The following were the chief features of the address of President John W. Lieb, general manager and vice president, New York Edison Co.:

ADDRESS OF MR. LIEB

Mr. Lieb pleaded for continuation of teamplay in the electrical industries, in which he included street railways, telephone, telegraph, light, power and the manufacturing enterprises. Mr. Lieb said there were about 920,000 men engaged in the industry which represents capital of about $10,750,000,000 and an output valued at $2,675,000,000 a year. The electric light and power industry employs about 125,000 men, the capital invested is $3,000,000,000, and the annual business done amounts to $575,000,000.

The industry, according to Mr. Lieb, is second only to the great national railway system. He regards "linking up" of systems first to further fuel economy as the most important problem now confronting the industry. The public utilities were urged to take the initiative in this and similar matters; otherwise, he said, Government control would follow.

The mounting costs of conducting business have left nothing for dividends and sometimes have not covered fixed charges, and in any case have left barely enough to cover operating expenses.

The coal shortage, Mr. Lieb claimed, was due to labor shortage at the mines, transportation breakdown, troubles at the tidewater terminals and to lack of coal cars. Experience in normal times has shown it unsafe to begin the winter with less than 30 to 45 days' coal supply; now one cannot hope to accumulate the 60- to 90-day supply that the uncertainties of the present make necessary. Fuel costs from 75 to 80 per cent. of the cost of current delivered to the switchboard and from 20 to 25 per cent. of the cost delivered to the customer. Further fuel economy is impracticable at this time, although advantage may be taken of the diversity factor between systems, operating with a common reserve, and of the assistance which one system may give another through interconnection.

It does not need demonstration to prove that the coal consumption in the isolated plant is generally from 2½ to 4 and 5 times the amount required to produce the same quantity of electrical energy in central stations. Parallel operation of street systems (central station) and isolated plant is hardly practicable, in Mr. Lieb's opinion.

He recommended keeping the clock advanced one hour the year round. Relative to the growing shortage of labor, he pleaded for exemption from military service of those specially trained unless, of course, they were going to use their special training in the service. The further employment of women is now a live problem, and one soon to demand attention is the training and employment of the wounded and blind returned soldiers.

The member companies have purchased to date $29,555,250 in Liberty Bonds and $1,467,945.69 in War Stamps.

MR. INSULL'S ADDRESS

The next address of importance to the industry broadly was made at the dinner, Thursday evening, by Samuel Insull, president, Commonwealth Edison Co., Chicago. Mr. Insull sounded the trumpet of hope and confidence in the industry. He said that relief from the burdens of high cost of conducting the industry could be had if the reasons for rate increases were properly put before the people in the various localities where rate increases were necessary. He based his belief upon the fact that in 1917 out of 467 applications for rate increases 400 decisions in favor of such increases were given by the public-utility commissions hearing the cases. With labor increasing its wage, cost of fuel increasing as part of Governmental action, and with supply and demand exerting their usual force, it does not seem possible that the industry can contemplate the selling price remaining stationary. Those conducting the industry must have confidence in their industry if investment bankers were to be expected to invest their money in it. The industry must conduct itself so as to get and to maintain the confidence of the constituted authorities and so pass this confidence on to investment bankers.

Relative to fuel orders Mr. Insull said that every order of Mr. Garfield reduced the central-station load factor and reduced returns. As to the "lightless night" order, cutting out all electrical display advertising, it effected the industry's earning capacity out of all proportion to the coal saved. But because of its awakening effect upon the people, Mr. Insull said he would have done as Garfield did.

The speaker urged that central stations drop extravagances of a capital character and of operating nature. This is not the time to consider balance sheets.

To make up for the shortage of coal cars all unnecessary forms of improvements must be postponed and the open-top car equipment used to transport the materials for such improvements used for hauling coal. There is not the time or the capacity to make all the new equipment needed; it must be taken from other channels not absolutely necessary.

ADDRESS OF MR. NOYES

P. B. Noyes, Director Conservation Division of the United States Fuel Administration pointed out the enormous physical proportion of the work the administration was doing. The cotton crop of a whole year could be moved in one day of coal movement, and thirty days of coal movement are equivalent to the movement of the coming second largest wheat crop. Eighty millions more tons of coal will be needed by the industries alone this year over last. America must mine 220 million tons in excess of that ever before mined in one year. "We need 100,000,000 tons more coal this year than last; if we mine half of it we will do well," said Mr. Noyes. The draft had taken away 35,000 coal miners.

Mr. Noyes says that classifying industries as essential and non-essential cannot be done; he divides them as war and nonwar. He pointed out that it was impracticable to cut off completely fuel to nonwar industries even when some war industries must go without it, because industrial dislocation, riots, strikes and great evils would follow if coal was unthinkingly withheld from many centers where there were few except nonwar industries. These industries, said Mr. Noyes, use less than 100 million tons of coal a year. One ton of coal meant keeping at least fifty people at work. That is one view he wishes persons to take of the coal situation.

We, the administration, must tell the public utilities as we told the steel people, namely: make the utility business 100 per cent., then you will get 100 per cent. coal, said Mr Noyes. The utilities must refuse service to those whose use of it is not more or less intimately associated with the winning of the war, and they must see to it that those using the service use it economically. The administration expects the utilities to do much of their own policing in respect to this field of conservation.

DOCTOR WHEELER'S ADDRESS

Dr. S. S. Wheeler made an illuminating address on training the blind to do work in the electrical industry. They are now successfully winding coils of stators and armatures at the same piecework rate paid sighted persons. Arthur Williams also spoke at the dinner; his subject was food conservation.

The Prime Movers Committee was represented only by N. A. Carle, all other members being absent. Mr. Carle is the new appointee to the committee, having taken the place of the late John P. Sparrow, of the New York Edison Co.

George A. Orrok gave a paper on "Location of Power Plants at the Coal Mines," and Philip Torchio, electrical engineer, New York Edison Co., had a paper on "The Utilization of Water Power as a Measure of Coal Conservation." The chief point of Mr. Torchio's remarks was that the East must depend upon steam for the great heat unit requirement of this section, as adequate water power is unavailable.

Charles E. Stuart, chief of power and light division, United States Fuel Administration, read a paper on "War Conservation of Power and Light," from which the following is taken:

General plans have been laid out for the conservation of light and power by the Bureau of Conservation of the United States Fuel Administration, of which P. B. Noyes is director, and these plans will be carried out by the Power and Light Division. They will be developed under the following subdivisions: (1) Elimination of Uneconomical Isolated Plants. (2) The Application of the Skip-Stop to Railways and the Regulation of Car Heating and Lighting. (3) Economy in Utilization of Power and Light in Factories. (4) Utilization of Excess Water Power and Interconnection of Power Systems. (5) Limiting the Production of Power to the Most Efficient Points Available. (6) Economy in the Refrigerating and Ice-Manufacturing Industry.

A brief statement with respect to each of these subdivisions is developed below.

The plans will be carried out through the coöperation of the following: *First*, a force of engineers organized and stationed with the Fuel Administration at Washington; *second*, the Engineering Department of the United States Geological Survey; *third*, the Power Division of the Council of National Defense; *fourth*, a state fuel engineer attached to the office of the State Fuel Administrator, to supervise the activities in his state; *fifth*, the public service commissions and state regulatory bodies; *sixth*, the chambers of commerce and similar representative business bodies; *seventh*, volunteer engineers located throughout the country.

The following gives the scope of the subdivisions:

1. Elimination of Uneconomical Isolated Plants

The individualistic way in which fuel is now consumed in cities is not efficient. A ton of coal burned in a large central station will produce at least four times as much electric power as if burned in the average small plant, and if centralized burning could be introduced to a greater extent, the amount of fuel required could be largely reduced without reducing in any way the ultimate production of light and power.

It is frequently the case that in buildings where electric plants are located and where exhaust steam is utilized in the heating of the building and in furnishing hot-water requirements, such buildings can adopt central-station service without a loss of money and at a saving in fuel.

As a rule it may be stated that where no extensive heating system is operated in conjunction with the generating plant, such a plant can purchase power at a great fuel saving and with a possible reduction in power cost. In other cases it would be more economical, from the viewpoint of fuel saving, to utilize central-station service in conjunction with isolated electric plants.

It is the duty of the Fuel Administration to devise means for securing a curtailment in the use of fuel in ways that will impose a minimum of hardship. It is believed that there are many plants, not only in New York but throughout the entire country, which could, at least temporarily, shut down their own electrical machinery and purchase power from others at a financial advantage to both parties and with a considerable saving in fuel.

The Fuel Administration believes that if even a comparatively small proportion of the plants throughout the country which could save fuel in this way at a profit to themselves would do so, it would prove a tremendous help in meeting the fuel situation with which the country is confronted, and in winning the war.

While it may appear that the interests of the central station are being benefited to a large degree, such is not of necessity the case. In some cases, central stations may be shut down. In any event any connection between a central station and a building or a manufacturing plant that is affected, will, of necessity, be for the period of the war only or through the period where the coal situation is critical. The machinery of the isolated plant can be readily preserved through this period of necessity. Under these circumstances the heavy expense attendant upon the making of the connection by the central station may completely or even more than offset any profit which could be expected of such a load through a short period.

2. Economy in Utilization of Power and Light in Factories

The United States Fuel Administration is requesting, as a means of accomplishing power and light conservation in manufacturing and industrial establishments, the appointment, by the management, of a Shop Committee, composed of those best suited for the purpose and in size or number suitable to the size of the plant, one member of this committee to act as its chairman; the committee to be active with and have charge of all details in the operation of the plant that would in any way contribute to economy in fuel or that in which fuel is used to produce, and report weekly to the management or head of the plant.

It is also suggested that this committee be changed from time to time, so that the spirit and interest in this work may be maintained.

It is not the purpose arbitrarily to outline in detail the method for doing this work, rather to suggest in a general way, leaving the details and adoption of the plan in the hands of the manufacturers interested, as we realize that conditions in different plants and character of manufacture, as well as organization, will have a bearing on the size, character and details of the committee, which must be suited to the particular case under consideration.

As a typical illustration of possible waste and opportunity for conservation, we suggest the following items: (1) Lights being unnecessarily burned; (2) lamps of too high candlepower; (3) the elimination of carbon lamps in favor of Mazda lamps where practicable; (4) the elimination of arc lamps and substitution of nitrogen-filled lamps, which are from two to three times as efficient; (5) the restricted use of sunlight due to dirty windows; (6) operation of motors when machinery is idle; (7) excessive sparking, heating or erratic speed of motors; (8) improper alignment of shafting; (9) grouping of machines so as to operate motors or engines as nearly loaded as possible; (10) staggering of operations so as to maintain as flat a load curve as possible; (11) slipping belts; (12) dry bearings; (13) overheated or underheated parts of plant; (14) excessive drafts due to lack of proper protection about openings of doors, windows, elevator and staircase areas; (15) the reduction of elevator service or the application of a skip-stop to elevator service; (16) the testing out of power circuits for relationship of capacity to load carried; (17) the paralleling of power circuits.

We also suggest that the work of this committee be conducted in such a manner as to provide records of savings, which could be incorporated in reports and information desired from time to time as to the progress of this work.

3. Utilization of Excess Water Power and Interconnection of Power Systems

A method of fuel conservation that promises a certain amount of immediate relief and at the same time opens up a field with almost limitless possibilities for future development is the interconnection of the present power systems of the country, and the consequent utilization of considerable excess water power which is at present available.

In many parts of the country duplicate transmission systems exist, serving practically the same territory. An interconnection between these systems for the mutual exchange of energy would, in many cases, result in marked economies. In other cases, the lines of a power company which derives all, or nearly all, its energy from water power may extend very close to the lines of another company which uses coal to a large extent for the generating of power. Since no company is so fortunate as to be operating with a 100 per cent. load factor, there are necessarily times during light load when the water-power company is forced to allow unproductive water to flow over its dam. At such a time a great saving in fuel would be effected were the two companies tied together and the load on the steam station transferred in part or entirely to the water-power plant. Numerous hydro-electric companies have for a long time been carrying out this idea within their own systems, where the bulk of their power is derived from water, and at the same time they maintain a steam reserve to carry their load during low-water periods.

In some cases these system interconnections would involve a considerable expenditure of both time and money, in which event they would not be subject to immediate aggressive action by the administration but would be held in abeyance as possibilities for future consideration and developments.

4. Limiting the Production of Power to the Most Efficient Plants Available

We have been able to locate nearly 500 instances throughout the country where there exists, in one form or another, a duplication of power production and supply. In other words, there are communities where two or more central stations are furnishing electrical energy with systems paralleling one another.

In certain instances the results of such a condition are not serious and in many cases probably unavoidable. Our investigations so far, however, have proved that a large percentage of these situations offer an opportunity for large fuel conservation.

5. Economy in the Refrigerating and Ice-Manufacturing Industry

In coöperation with the Joint Commission on Refrigeration, which was organized to assist the Government during the war, the Power and Light Division is planning to get in touch with the entire ice industry to introduce a number of proved economies in the operation of ice-and-refrigerating plants.

A number of suggestions have already been made by the commission and by individuals connected with the industry. One plan that possesses merit and has possibilities of considerable fuel saving is that of allotting a definite amount of coal to individual plants, depending upon the size and type of plant, such allowances being based upon a reduction of 10 to 15 per cent. of the average present fuel consumption. This will make it necessary to adopt many simple measures of economy that are now being overlooked.

Another possibility is that of producing white or opaque ice at a fuel saving of 5 to 20 per cent. This is accomplished by eliminating the power that is generally used for agitation in raw-water plants and for producing distillate in distilled-water plants, both of which are merely means of producing a transparent product. This measure is possible of adoption in many territories.

A further line of effort which will be productive of considerable economy and one that was successfully applied last winter is that of operating during the winter season only the most efficient plant, or plants, as the particular case requires, in communities where, during the summer season, all plants are required. This can be done and the individual business of each manufacturer will not be interfered with, as the arrangement provides that the operating plant or plants will sell at wholesale rates to those manufacturers whose plants are temporarily closed down.

This arrangement also produces a saving in ammonia, and for this reason was applied last winter at the request of the Food Administration.

W. W. Nichols, of Allis-Chalmers Co., gave the following in his paper on "The Development of Water Power as a War Measure":

The year 1917 was one of inferior demand in water-power machinery, yet 1,058,000 hp. of hydro-electric machinery was built and installed. This alone represents a saving of 8,500,000 tons of coal, besides a saving in production labor and transportation. Ten per cent. of the estimated coal shortage of this year therefore would be met if the industry could do as well this year. Without building new plants there are two ways of hydro-electric development: (1) By increasing the capacity of plants already built. In this connection it has been estimated that 300,000 hp. can be developed in the next twelve months by central stations. (2) Replacement of machinery installed prior to 1911. This would take care of an increased horsepower of 450,000. By these means 6,000,000 tons of coal would be saved in the twelve months in addition to labor and transportation. Power is now more than ever fundamental to cur existence. The power shortage is a national calamity, calling for a broad national treatment.

The convention visited the shipyards at Hog Island Saturday.

W. F. Wells, vice president and general manager of the Edison Electric Illuminating Co., Brooklyn, N. Y., was elected president of the association.

New York State Convention, N. A. S. E.

The New York State Association of the N. A. S. E. held its twenty-third annual convention at Coney Island, June 13-15. The Shelburne Hotel on the boulevard at Ocean Parkway was the headquarters. There were fully seventy-five delegates present. The business sessions of the convention were held in the balcony on the second floor of the hotel. The front portion of the main dining room was artistically decorated and conveniently arranged for the mechanical display. From the exhibitors' standpoint the arrangements for their convenience and comfort outclassed anything in the history of the state association. There were 52 companies represented. The meetings of the delegates were unusually interesting this year, and much important business was dispatched in the three days.

The opening ceremonies of the convention took place on Thurday evening. John B. McGowan, chairman of the local committee, delivered a brief though earnest address on the needed efficiency of the members of the N. A. S. E. in the present crisis. He then introduced Judge Henry Goldfogle,

SOME OF THOSE IN ATTENDANCE AT THE NEW YORK STATE N. A. S. E. MEETING who welcomed the delegates to the city, congratulated them on the preamble of the organization, and told them of the responsibility which now rests upon the engineer. George Van Vechten responded for the delegates, and Fred Felderman spoke of the necessity of closer attention to the educational work of the members of the N. A. S. E. The meeting was then adjourned until Friday morning at 8 o'clock.

On Friday morning the ladies were taken on an automobile sightseeing trip, and in the afternoon enjoyed a vaudeville show at Henderson's theater.

One of the features of the convention was the banquet on Friday evening, attended by the delegates, supplymen and ladies; covers were laid for two hundred. During the dinner Monroe Silver, Billy Murray, Bob Jones and Jack Armour entertained.

At the final meeting on Saturday evening the delegates elected the following state officers: P. H. Cassidy, Brooklyn, president; Robert Tobin, Troy, vice president; William Roberts, Yonkers, secretary; William Downs, New York, treasurer; W. B. Wear, Middletown, conductor; F. J. Desmond, Rochester, doorkeeper; A. T. Bennett, Brooklyn, chaplain; Samuel Thackerberry, New York, state deputy.

Next place of meeting Troy, N. Y., in June, 1919.

The retiring state president, George C. Van Vechten, was the recipient of a mahogany clock, and Mrs. Van Vechten received a dressing-table set of cut glass.

The memorial services were conducted by the Rev. Arthur H. Cummings.

Annual Convention of American Boiler Manufacturers' Association

The American Boiler Manufacturers' Association held its thirtieth annual convention at the Bellevue-Stratford Hotel, Philadelphia, on June 17 and 18. At the opening session on Monday morning, the president of the association, M. H. Broderick, addressed the convention. He was followed by Dr. E. J. Cattell, city statistician of Philadelphia, who welcomed the association to the city. D. M. Medcalf, chief inspector of steam boilers, of Toronto, was called upon to speak and told of the part that Canada was playing in the furtherance of war work. William H. Barr, president of the National Founders' Association, next addressed the delegates, after which Dr. D. S. Jacobus, of the Babcock & Wilcox Co., gave a talk on furnace and combustion chamber volumes, illustrated by blackboard sketches. *Power* hopes to present the main points of Dr. Jacobus' talk in a later issue.

At Monday afternoon's session, E. R. Fish presented the financial report of the committee on uniform boiler laws. The work accomplished by this committee during the past year was outlined by Charles E. Gorton, who said that since the 1917 convention seven states had adopted the A. S. M. E. Code. In Kentucky active support had been obtained and a campaign was being organized to submit a bill to the state legislature. In Louisiana legislation had been introduced, calling on the governor to appoint a committee to investigate the desirability of adopting the A. S. M. E. Code and to report its findings to him. The Merchants' and Manufacturers' Association of Baltimore had been interested in the matter and a bill will be introduced at the next session of the Maryland legislature. The governor of Missouri has recognized the importance of adopting a uniform boiler law and favorable action is expected on the bill that is to be introduced in that state. In South Carolina the work moves slowly, but in due time the state may take up the matter. In Virginia it is expected that the bill will be reported out of committee at the next meeting of the legislature. Montana appreciates the need of such a law, and is in a favorable position to act on it, as the Industrial Accident Board is able to put the law into effect. Iowa is in the same state of mind and the legislature is expected to act favorably. Progress is being made in Massachusetts, but in Rhode Island the bill was not reported out of committee. In Vermont and New Hampshire the prospects are good. In Georgia the Manufacturers' Association is pledged to further the interests of a bill to adopt the A. S. M. E. Code.

C. O. Meyer, deputy inspector of the State of Ohio, presented a communication from his department, pointing out that the A. S. M. E. Code fails to cover vertical-flue boilers and track locomotive boilers, and that as a consequence it had been necessary to ignore the A. S. M. E. Code and use the rules of the Interstate Commerce Commission. He intimated that Ohio might return to its own rules, in force before the adoption of the A. S. M. E. Code, and suggested that the chairman of the American Uniform Boiler Law Society be a man who is neither a member of the A. S. M. E. Code Committee nor a boiler manufacturer.

A letter from the United States Board of Supervising Inspectors pointed out that their own inspection rules had been in use for sixty years, had met all conditions, were efficient and safe, and for those reasons the board declined to adopt the A. S. M. E. Code instead.

The vice president of the association, C. V. Kellogg, gave an exceedingly earnest and stirring address. He pointed out the folly of individualism and the necessity of organization and coöperation among boiler manufacturers to meet the industrial conditions that would follow the war, particularly the labor crisis that was sure to arise. C. J. Champion, who followed him, also took coöperation as the theme of his remarks, and described how it could be obtained and the results it would produce.

Col. F. N. Gunby, U. S. A., gave a very interesting account of the methods employed in building the various cantonments and the difficulties to be overcome. His talk was illustrated by lantern slides and moving pictures showing construction work in progress and in various stages of completion.

On Tuesday morning, G. S. Barnum presented the report of the committee on uniform costs. He outlined a simple cost-keeping system, laying particular stress on the method of distributing overhead charges. Charles A. Howard, who spoke next, disagreed with Mr. Kellogg on some points. He insisted that a cost system had other uses besides showing how much profit to charge. At the close of his speech, the president announced that Charles M. Schwab, director general of the Emergency Fleet Corporation, had just arrived and would address the convention. As Mr. Schwab entered the convention hall, he was given an enthusiastic welcome by the delegates. In responding to this ovation, he impressed upon the boiler manufacturers the important part they must take in the success of the shipbuilding program, inasmuch as the lack of accessories is the greatest cause of delay. From 80 to 90 per cent. of the hulls now afloat are waiting for engines, boilers or other accessories. Mr. Schwab said that beginning with July 1 he expected to publish a list of the relative performances of all the shipyards in the United States, showing those which had done the best as well as those which had fallen short of expectations, so that the American people should know exactly where to place praise or censure. Further, he said he intended to ask Congress to authorize service medals, to be awarded for industrial work to those concerns that have done and are doing their best to aid in winning the war. By this means he hopes to give public recognition of the services of those who deserve it because of their efforts and achievements in the industrial promotion of war tasks.

At Tuesday afternoon's session, Hon. Edwin F. Sweet, Assistant Secretary of Commerce, addressed the delegates on the subject, "Some Compensations of the War." He showed that as a nation we will benefit from the war by becoming more economical; that we shall increase production both in industry and in agriculture; that we shall learn the forgotten trade of shipbuilding and develop a vast merchant marine to serve a great foreign trade; that we shall learn how to guard against the ravages of preventable diseases; that our inventive genius will be spurred to greater achievements; and that both individual and national character will receive a wonderful uplift.

W. C. Connelly, chairman of the committee on war service, reported as to the work accomplished by that committee. It had sent out questionnaires to boiler manufacturers throughout the country and had received responses from

95 per cent. From the information thus obtained, the equipment and manufacturing facilities of practically every boilermaking establishment had been listed. This information was sent to all the various Government departments to which it could be of service.

The nominating committee presented the list of nominees for officers of the association, as follows: President, W. C. Connelly; vice president, C. V. Kellogg; secretary-treasurer, H. N. Covell; executive committee, M. H. Broderick, G. S. Barnum, W. J. Moore, E. C. Fisher and Dr. D. S. Jacobus. They were unanimously elected. The place of the next convention was left to the decision of the executive committee.

N. A. S. E. Iowa State Convention

On June 12-14 at Cedar Rapids the Iowa State Association of the National Association of Stationary Engineers held its fifteenth annual convention. It was an unqualified success notwithstanding the busy times and war conditions. Over one hundred engineers were registered and with the Ladies' Auxiliary and the exhibitors the attendance was exceptionally good. The exhibits were up to standard and the program made up by the convention committee was carried through with enthusiasm. Headquarters was at the City Auditorium, where the sessions were held and the exhibits displayed.

With F. W. Laas, state president, in the chair, the convention opened Wednesday afternoon. Mayor J. F. Rall gave the address of welcome. He was pleased to notice that the organization stood for education. It was a rare exception in these days to find an institution that was not organized for raising salary. The mayor spoke of the Cedar Rapids adjustment plan which called for arbitration in any dispute between capital and labor. It was his hope that the visiting engineers would find many things of interest in the city.

F. W. Raven, national secretary, responded. He informed the mayor that he was facing a small cog of a great organization that had done much in the last thirty-five years to conserve national resources. Briefly he outlined the educational methods employed. The day had come when the older engineers must show the results of the training the organization had given them and the younger members must take full advantage of the opportunities offered. The Government needed the best services of all.

For the first time in the history of the organization a national president had visited the state and was in attendance at the convention. The honor was appreciated and those present listened with interest to a brief address by John A. Wickert. In his opinion the engineer had the opportunity to be the man of the future. He was recognized more than ever before, as a man belonging to a profession. Those engineers who did not wake up to their responsibilities would find that other men would supplant them. Mention was made of the power-plant cost-data system that had been added to the educational program and of the help it would be in filling out intelligently the Government questionnaire. The president bespoke a big attendance at the national convention, where the educational features were to be the big thing and the entertainment secondary. Good delegates were requested—men who could bring back intelligent reports.

A patriotic address by James E. Bromwell, of Marion, was the event of the evening session. It was of exceptional quality and was commented upon highly by all present. "How many of you are true soldiers?" was the opening remark of National President Wickert. "Last year millions of tons of coal were wasted. Are you doing your share to conserve it?" The whole country is demanding service and none were better prepared than the engineer to give it. It was obligatory upon the engineer to attend meetings and better prepare himself for the work demanded. Subscriptions to the Red Cross and the buying of Liberty Bonds was not enough. Each engineer must recognize his responsibility and learn to do his work to the best possible advantage.

National Secretary Raven reminded the engineers that all of them were drafted. Each had his work, and his efforts had just as much to do with the results of the war as those of the men at the front. Dancing followed, with music by the Laas orchestra.

At the Thursday morning session J. H. Coates lectured on condensers. He outlined the theoretical possibilities of the condenser and told why maximum results could not be obtained in practice. The two general types, surface and jet, were discussed, the latter type including the low-level or ejector condenser and the high-level jet condenser of the barometric type. The construction, advantages and disadvantages and the auxiliaries required were given attention in each case, and some mention was made of the recent advances in cooling-tower construction.

J. M. Drabelle, of the Iowa Railway and Light Co., had an ascilograph at the hall. It was in running order and each engineer had an opportunity to see the wave line of the particular circuit to which it was attached. At the meeting its action was briefly explained and the speaker told how instantaneous information given by the instrument, and not available from the ordinary switchboard instruments, helped to locate troubles at the plant or in the line.

R. H. Holbrook, president of the local association, talked on fuel. In the United States about 1,900,000 tons of coal per day had been mined, while 2,300,000 tons would be required to carry on all industries satisfactorily. There would be a daily shortage of 400,000 tons of coal, or 120,000,000 tons per year of 300 days. He enjoined engineers to use their heads and to follow Government advice given in

MEMBERS AND THEIR GUESTS ATTENDING THE FIFTEENTH ANNUAL CONVENTION OF THE IOWA regard to coal economy. Transportation difficulties and the zone system were reviewed and the Iowa situation discussed. In Iowa boys' help was counted upon to solve the labor problem at the mines. If handled right Iowa fuel would give excellent results. With the moisture and ash out it was better than Illinois coal and as good as the fuel formerly obtained from Kentucky. It was a question of learning how to use it, and in this connection the campaign of a year ago would be continued.

Thursday afternoon and evening were given over to the exhibitors. In the evening the feature was a smoker.

The last session of the convention on Friday morning was given over to committee reports and routine business. The license law committee was instructed to coöperate with other engineering bodies with a view to the enactment of license legislation. A motion calling for discontinuance of the state convention until the war is over, was lost. State Deputy Holbrook reported relatively large increases in several associations of the state and urged to greater effort the locals that had not shown a gain. National Secretary Raven reviewed the work of the national association up to date. Up to the present the finances were ahead of those of last year. He emphasized the necessity for careful selection of officers and delegates and in general pointed out the duties of all.

As the next convention city Marshalltown had no opposition. The following officers were elected: Robert Mullin, president; P. H. Heise, vice president; Abner Davis, secretary; J. A. Coulson, treasurer; R. Moore, conductor; S. C. Dike, doorkeeper; R. H. Holbrook, state deputy.

Firms having display space at the convention were: American Engineering Co., American Steam Conveyor Corporation, Anchor Packing Co., Baker Valve Co., Cedar Rapids Pump Co., Crandall Packing Co., Crane Co., Dearborn Chemical Co., The Fairbanks Co., Fisher Governor Co., Garlock Packing Co., Gustave Lidseen, Hawk-Eye Compound Co., Hays Instrument Co., Hills McCanna Co., International Correspondence Schools, Jenkins Bros., H. W. Johns-Manville Co., Lunkenheimer Co., Murray Iron Works Co., Reordway Co., Sinclair Refining Co., Standard Oil Co., Viscosity Oil Co., Wehlage Electrical Co., Western Boiler Compound Co.

War Industries Board Moves to Obtain Capital for Power Plants

The War Industries Board has sent to Congress the draft of a proposed bill to appropriate $200,000,000 to increase the power supply in overloaded industrial centers of the East. Cities along the Atlantic Seaboard in which munitions and materials for war are being manufactured would be the especial beneficiaries under the measure, which has been committed to the care for the present of Representative Kitchin, chairman of the House Ways and Means Committee, on the House side, and of Senator Martin of Virginia, chairman of the Appropriations Committee, on the Senate side. The measure, it is understood, was drafted by Frederic Darlington, chief of the Power Plant section of the War Industries Board, at the request of Bernard M. Baruch, chairman of the board, and it is said to have the backing of President Wilson.

The measure is frankly emergency legislation, made necessary by the apparent need of the industrial section of the East for more power with which to turn out munitions of war. It is stated in Washington that the power supply of the East is obviously overloaded, and that while different sections of the country are also raising the question of not having sufficient power with which to turn out the munitions and material needed by the Government, it is the intention of the War Industries Board to see that the East is supplied first, and then endeavor, perhaps by additional legislation and appropriations, to supply other sections of the country. Until recently, it is stated in Washington, power companies with insufficient equipment, and without sufficient funds to purchase equipment, had expected to be assisted in obtaining capital and equipment through the War Finance Corporation, but now that that body has ruled in a manner which makes it unlikely that power companies can be so supplied, the need for empowering legislation of a specific and emergency character becomes apparent as one of the necessities for winning the war. It is said in Washington also that some of the power companies have come to see that if money is borrowed now for additional equipment which might not be needed at the end of the war, they would be doing themselves more harm than good in so borrowing money and increasing plant facilities.

Plans for passing the legislation desired have not been worked out in Congress, and until the proposed emergency legislation is introduced the War Industries Board is not likely to be able to make plans for the distribution of the capital when obtained. It is said in Washington that much more than the $200,000,000 now proposed to be appropriated will be needed, inasmuch as in the Pittsburgh district alone, which supplies power for a radius of 100 miles, it is estimated that $40,000,000 or $50,000,000 for additional plant facilities might be needed. The War Industries Board is now making a census of the various power needs of the different localities in the country engaged in war work. It is expected by the Washington correspondent of *Power* that the proposed emergency legislation will be difficult of passage in Congress, although it is admitted on all sides in Government industrial circles engaged in obtaining war material that some such legislation is needed at once.

STATE ASSOCIATION OF THE NATIONAL ASSOCIATION OF STATIONARY ENGINEERS AT CEDAR RAPIDS

Improving Plant Efficiency at Both Ends of the Steam Cycle

On June 17, at a joint meeting of the Western Society of Engineers and the Chicago sections of the American Society of Mechanical Engineers and the American Institute of Electrical Engineers, two important papers having a bearing on fuel conservation were presented. The attendance was large and the material presented was received with unusual interest. The first paper on "Advantages of High Pressure and Superheat as Affecting Steam Plant Efficiency," by Eskil Berg, of the General Electric Co., dealt with the improvements in economy to be obtained at the upper end of the steam cycle, while D. W. R. Morgan, of the Westinghouse Electric and Manufacturing Co., in his paper on "Condensers" showed how better results could still be obtained at the lower limits of the cycle. Both papers with the discussion will appear in later issues of *Power*. Briefly, Mr. Berg showed that a more efficient turbine was obtained by a combination of high pressure and superheat, the latter being necessary to obviate as much as possible the troubles arising from condensation in the turbine. In Europe steam temperatures of 700 deg. and higher are common. In this country boilers have been built for 350 lb. pressure and for a certain installation in England, B. & W. boilers were designed for a working pressure of 500 lb. With a superheat ranging from 200 to 300 deg., the final steam temperature would reach 800 deg. This would necessitate smaller tubes in the boilers, redesigning of the auxiliary equipment and elimination of joints by welding the piping system solid.

The salient features of the two general types of condenser, surface and jet, were brought out by Mr. Morgan. The three principal losses are drop in vacuum through the condenser, difference in temperature between the steam and condensate and incomplete air removal. The speaker pointed out where improvement is possible and compared the various auxiliaries in common use, such as circulating pumps and air pumps of the reciprocating, hydraulic and steam-ejector types. Owing to the shortage of copper the Government is seriously considering the elimination of the surface condenser for the period of the war. The effect on the coal pile must of course be considered, but the great saving in material by the use of jet or barometric condensers demands attention. With proper steps toward eliminating the action of the water, steel tubes might be used to advantage in surface condensers. In heat transfer the time element would be an important factor and would call for low circulating-water velocities.

There Should Be No Letup During the Summer Months*

With the advent of the hot weather a falling off in the sales of Thrift and War Stamps may be expected unless the efforts of the patriotic workers are not suffered to diminish. There need be no falling off in the sales, however, if we all keep our heads and continue to view the situation sanely and clearly. Let each one of us ask himself or herself whether the need for our coöperation is as great among the Allies as it was and then, when we have answered our own question in the affirmative (and who could answer it otherwise?), let us make up our minds at once that while the need exists the money shall be supplied. There were a million reasons advanced during the last Liberty Loan campaign why everyone should subscribe and induce others to do likewise, and there was not a reason advanced at that time that does not apply with just as much force to the War Savings Stamps now.

Someone may say, "But I've bought stamps until I'm almost broke," and they may really feel that they have a valid reason for not buying more, but people who talk like that have failed to grasp the significance of the situation. Such people do not stop to consider their sacrifices as compared to the sacrifices that are being made daily, hourly by the young men of America who are on the firing line in Europe.

There really should be no need to plead with anyone to buy stamps and thus have a part, though a small one, in this the greatest movement in the history of man. Every individual should consider this not alone a duty, but a great privilege. Now, viewing the matter from another angle, divesting the question of all sentiment, patriotism and obligation, let us consider it as a matter of dollars and cents.

And let us remember right at the start that we are not giving, we are receiving. We lend on the best security in the world and in five years the loan is returned with interest. But that is not all. Let us also remember that after peace has been restored and conditions return to normal the purchasing value of the dollar will be greater by far than it is now, so that every dollar saved now will doubtless do the work of two or more in a few years.

There is nothing new in the foregoing, but for the sake of emphasizing the importance of the War Savings Stamp campaign let us continue to keep this important matter before the people.

National War Savings Day

Every loyal American is being called upon to sign a War Savings Stamp pledge card that is in effect a renewal of the promise of loyalty that arose, consciously or unconsciously, from the heart of every American when the news came from Washington a year ago that we had entered the conflict and ranged ourselves on the side of civilization against the forces of destruction. The pledge card also means that the signer takes up anew the fight against extravagance and waste, which are enemies as deadly to the cause of the Allies as any bullet that wings its way from the German lines.

Remember this: You take no chances when you go the limit on War Savings Stamps. They are the best and safest investment in the world. They pay you 4 per cent. interest, compounded quarterly. They can't go below par. You can get back every dollar you put into War Savings Stamps any time you need it. You can turn them in at the Post Office any time for their full value plus interest.

Uncle Sam is asking hundreds of thousands of men to give their lives to their country. He is asking you only to lend your money. What are you lending?

June 28 is National War Savings Day. That's the day we sign up, telling Uncle Sam just how much we can or will do to help win the war. You are expected to pledge the full amount that you can afford to use to buy War Savings Stamps during the remaining half of 1918.

In every state, county, city, town and village the War Savings committees have prepared for this big patriotic rally day. Unless you have already bought W. S. S. to the $1000 limit, get busy and figure out the utmost you can do.—*W. S. S. Committee.*

Establish United States Service Clearing House for Engineers

Placement of engineers as civilians in any and all Government departments as well as in private positions will be the function of the newly established service clearing house in Chicago of the United States Employment Service of the Department of Labor. For some time a division of education has been operating, and this week a division of engineering was initiated with the appointment of A. H. Krom as director, reporting to Dr. P. L. Prentis, district superintendent. Offices have been taken at 29 South La Salle St

After graduation as an electrical engineer from Purdue University in 1910, Mr. Krom was for three years with the Commonwealth Edison Co., one year chief engineer of the Haskins Glass Co., two years power engineer of the Central Illinois Public Service Co., two years with the Illinois Public Utility Commission, one year assistant engineer at Springfield and one year as engineer in charge of the Chicago office. For the last 18 months he has been secretary of the American Association of Engineers.

*From New York "Evening Sun."

National Coal Association's Program To Increase Coal Output

The National Coal Association issued the following statement June 15:

The National Coal Association, composed of bituminous operators, whose annual output exceeds 350,000,000 tons, has undertaken a program of maximum effort to increase production and minimize the serious results of the threatened shortage in coal next winter which now appears to be almost inevitable.

The entire membership of the association, consisting of approximately two thousand coal-mine owners and operators, is undertaking by scientific management and in other ways to increase production to the greatest possible total. A coal-production committee, of which A. R. Hamilton, of Pittsburgh, is chairman, has been appointed by the Board of Directors with instructions to coöperate to the fullest extent with the Fuel Administration and to comb the industry for practical ideas and suggestions to increase the amount of coal mined during the coming summer and fall.

Every producing field in the country is represented on the committee. Meetings will be held in Washington, beginning at an early date and continuing practically without interruption. Problems confronting the industry will be studied carefully, and constructive steps looking toward greater efficiency will be put into effect wherever possible.

At its annual convention in Philadelphia last month, the association pledged to the Fuel Administration its wholehearted support and endeavor in producing a maximum output. The appointment of the coal-production committee and the great program confronting the committee are an earnest of the intention to fulfill that pledge.

Mine output has been restricted greatly in the past by the shortage of railroad cars at the mines. To this dominating factor in curtailing production have recently been added others, among them being difficulty in securing sufficient labor and mine supplies. The coal operators realize that the situation confronting the nation is a serious one, calling for the best thought of the industry; the problem of producing more than 12,000,000 tons of coal weekly—an output never reached before—is no little one; but nothing that can be done will be left undone to mine coal.

New Publications

FUEL ECONOMY IN THE OPERATION OF HAND FIRED POWER PLANTS

The scarcity of coal last winter and the recent warnings of the Fuel Administration regarding the possibility of a shortage next winter emphasize the need for greater economy in the use of fuel. The present high rate of production is still insufficient to supply all needs, and there seems to be no possibility of an increase in the output of the mines sufficient to satisfy every demand. There are two possible results of this fuel shortage; either certain industries must close down or more work must be done with the coal available. The Engineering Experiment Station of the University of Illinois has issued a 90-page booklet printed in four colors which shows that the average small power plant can save 15 per cent. of its fuel by the exercise of greater care in equipment and operation. This means a saving of 12 or 13 million tons per annum if applied throughout the country. The purpose of the publication is to present to owners, managers superintendents, engineers and firemen certain suggestions which will help them in effecting greater fuel economy and in determining the properties and characteristics of the coal purchased. Features of installation essential to the proper combustion of fuel are discussed, the practice to be observed in the operation of the plant is outlined, and the employment of simple devices for indicating conditions of operation is prescribed.

Only a limited supply of copies of this publication is available for free distribution. Requests for copies should be directed to the Engineering Experiment Station, Urbana, Ill., and should specify "Circular No. 7."

Miscellaneous News

An Economizer and Boiler Exploded in the central power plant of the New Orleans (La.) Railway and Light Co. on June 10, injuring eight men, two probably fatally, and plunged the city into almost total darkness for nearly an hour. The business section of the city was kept lighted through sub-stations. The damage is estimated at $50,000. A fuller report of the accident will appear in a coming issue.

Feather River Development—The development of hydro-electric properties along the Feather River is the principal feature of the program of the California State Railroad Commission to increase the electric power production of the state. The plan suggested by the Railroad Commission includes the joint development by the Great Western Power Co. and the Pacific Gas & Electric Co. of the tremendous power possibilities along the Feather River. The work as proposed would mean the expenditure of at least $30,000,000. Government financing for the development is proposed.

Millions Saved by Daylight.—France, it is understood, estimates her saving in lighting and fuel alone by the daylight saving plan at not less than $10,000,000 a year. England is reported to have saved gas and electricity to the extent of about $12,000,000, and actually saved 300,000 tons of coal in the summer of 1916. Edinburgh saved $50,000 in fuel alone. Manchester, England, decreased lighting cost 15 per cent. over the previous year, and Nottingham 25 per cent. In Vienna the saving in lighting bills was $142,000. The estimated possible saving for the United States for the five months under this plan is placed at from $25,000,000 to $50,000,000 in lighting bills, and in fuel several million more.

Continued Failure of Coal Transportation—The failure of car supply at the coal mines still continues as is evidenced by conditions at the properties of the W. S. Barstow & Co. The normal supply should be at the rate of 266 cars per month and at no time during the past seven months has it been 50 per cent. The actual record is as follows:

	Cars
November	129
December	80
January	52
February	70
March	101
April	115
May	124

Unless there is a pronounced improvement in car supply in the next four months there is no doubt that the coal experience of last fall will be repeated during the coming winter, even though the winter may be a mild one.

Business Items

The Westinghouse Electric and Manufacturing Co., Pittsburgh, Penn., has purchased the property, business and good will of the Krantz Manufacturing Co., Inc., Brooklyn, N. Y., manufacturers of safety and semisafety electrical and other devices. The supply department of the Westinghouse Electric and Manufacturing Co. will act as exclusive sales agent for the products of the Krantz Manufacturing Co., whose business will be continued under its present name. H. G. Hoke, of the former company, will represent the supply department at the Krantz factory.

NEW CONSTRUCTION

PROPOSED WORK

R. I., Woonsocket—W. F. Fontaine, Arch., 285 Main St., is in the market for motors, etc., in connection with the erection of a 3 story spinning mill on Cass Ave.

N. Y., Hudson—B. Wenzel is considering plans for the erection of an electric lighting plant. Water from Lake Charlotte will be used to generate the power.

N. Y., Kings Park—The State Hospital Commission received bids June 12, for the installation of a heating system, etc., for the Employees' Home at the Kings Park State Hospital, from the W. B. Armstrong Heating Connections Co., 3 Fulton St., Albany, $20,966; Murtaugh & Reddington, 26 Pleasant St., Rochester, $22,500.

N. Y., New York—The Bureau of Yards & Docks, Navy Dept., Wash., D. C., plans to install boilers and superheaters at the Navy Yard, here. Estimated cost, $100,000.

N. Y., Olean—The Board of Armory Commission, 158 State St., Albany, received low bids for the installation of a heating system in its proposed 2 story, 52 x 110 ft. armory, from Hickey Bros., 256 North Union St., $4574; W. H. Simpson, 184 North Union St., $4853; Murtaugh & Reddington, 26 Pleasant St., Rochester, $7500. Noted June 4.

N. Y., Peekskill—The Village is in the market for new pumping apparatus. H. W. Taylor, 26 Cortland St., New York City, Consult. Engr.

N. J., Newark—The American Oil and Supply Co., Lafayette St., will soon receive bids for the installation of heating, lighting and plumbing systems in the proposed 1 and 2 story warehouse. P. B. Taylor, Essex Bldg., Engr.

N. J., Pompton Lakes—City will receive bids until July 2, for the erection of a brick and concrete power plant near the Pompton Lake Dam. Equipment including 2 turbine engines, electric switchboard, etc., will be installed. Estimated cost, $42,000. Noted June 4.

Penn., Hillsville—The Bessemer Limestone Co., Bessemer, plans to install an electric haulage system in its plant here. Estimated cost, $60,000.

Wash., D. C.—The Bureau of Accounts and Supplies, Navy Dept., Wash., D. C., will soon award the contract for machine and machine tools as follows:

(Item 1) two 15 hp. electric motors, 900 r.p.m.

(Item 2) one 15 hp. electric motor, 1200 r.p.m.; Class 397, Schedule No. 4704½.

Wash., D. C.—Bids will be opened June 25, by the Bureau of Supplies and Accounts, Navy Dept., for machines and machine tools:

(Item 1) 2 motor driven, double spindle, threading bolt machines; Class 423, Schedule No. 4733½, delivery Navy Yard, Norfolk.

(Item 1) 1 motor and drum type controller and pulley; Class 427, Schedule No. 4735½, delivery Navy Yard, Brooklyn.

June 28. (Item 1) 1 motor driven, cylinder grinding machines; Class 434, Schedule No. 4720½, delivery Navy Yard, Boston.

(Item 1) 10 turbo generating stes, 200 kva., 220 volt. a.c., 3 phase, 60 cycle; Class 432, Schedule No. 4738½, delivery Brooklyn, N. Y.

Va., Hampton—The Bureau of Yards and Docks, Navy Dept., Wash., D. C., plans to install boilers and superheaters at Navy Yard, here. Estimated cost, $90,000.

W. Va., Mabie—The Randolph Smokeless Coal Co., is having plans prepared for the erection of a new plant near here. Electrical equipment will be installed. Total cost, $100,000. A. F. Bennett, Philippi, Pres.

Ga., Flovilla—City plans an election soon to vote on $25,000 or $30,000 bonds for the erection of an electric lighting plant and a water works system.

La., Cheneyville—City plans an election soon to vote on $16,000 bonds for the construction of an electric lighting plant and a water works system.

Tenn., Nashville—Morgan & Hamilton, 1400 8th Ave., N., plans to install motor driven machinery in its new addition now being constructed.

Ky., Seurgeant—The Whitley-Elkhorn Coal Co. plans to install electrical equipment in its plant here.

Ohio, Akron—Summit Co. received low bids for installing a heating system in the proposed 2 story dormitory addition to the Children's Home, from the Akron Plumbing and Heating Co., 73 West Exchange St., $3645; the Industrial Heating and Engineering Co., 413 Ohio Bldg., $3785; the H. P. Cahill Plumbing and Heating Co., 4 South Canal St., $3975.

Ill., Chicago—The Illinois Central R.R., 135 East 11th St., plans to install a low pressure steam heating system, direct radiation, in its proposed through depot on 53rd St. A. S. Baldwin, Ch. Engr.

Ill., Chicago—The Trustees of Sanitary District, 910 South Michigan Ave., received low bids (a) building a sewage pumping station, (b) furnishing 6 centrifugal pumps with auxiliary machinery, piping, etc., (c) one 72 in. centrifugal pump, complete, (d) 8 synchronous motors, exciters, etc., (e) switchboard, conduit and wiring, from T. J. Forschner Contg. Co., West Pullman. (a) $922,278, (b) $231,000, (c) $65,000, (e) $50,000; Nash Bros., 10 South La Salle St. (a) $1,547,000; Nash-Dowdle Co., 29 South La Salle St., (a) $1,396,653, (b) $230,000, (c) $16,000, (e) $47,500; Camden Iron Works, Linn and Coppers Creek, Camden, N. J. (b) $254,300, (c) $46,000; The Electric Machinery Co., 14th Ave. and Tyler St., Minneapolis, Minn. (d) $120,000; General Electric Co., 53 West Jackson Blvd. (d) $123,494; Westinghouse Electric and Manufacturing Co., Indiana Harbor, (d) $131,000; Beaver Electric Constr. Co., 30 North La Salle St., (e) $49,495.

Wis., West Milwaukee (Milwaukee)—The Globe Seamless Steel Co., Colby Abbott Bldg., is in the market for three 10 ton electric cranes in connection with its proposed 1 story factory. F. J. O'Brien, Gen. Mgr.

Kan., Baxter Springs—The Big Lead Mining Co. will build a concentration plant and install air compressor, engines, boilers, etc., in same. Estimated cost, $60,000. J. E. Hoshal, Supt.

Kan., Baxter Springs—The Cortez Mining Co., Jefferson City, Mo., will build a power plant, etc., near St. Louis, Okla. Equipment including a 125 hp. boiler, motors, pumps, etc., will be installed in same. Total cost, $68,000.

Kan., Newton—The City plans to build a sewage disposal plant and install two 300 gpm. motor driven centrifugal pumps, etc. in same. Black & Veatch, 502 Interstate Bldg., Kansas City, Mo., Engr.

Kan., Pittsburg—The Joplin and Pittsburg R. R., 1st National Bank Bldg., Kansas City, Mo., plans to build power houses and a 45 mi. transmission line from here to Columbus, Kan., and Miami, Okla., in connection with the construction of the new electric railway. Estimated cost, $400,000. E. E. Maxwell, Pittsburg, Ch. Engr.

N. D., New England—The Aaby Light and Power Co. plans to build an electric lighting plant and a flour mill.

Mont., Saco—D. T. Gilbert plans to extend and improve his electric lighting plant here.

Mo., Badger—The Badger Mining and Development Co. is in the market for belts, engines, boilers, etc., for installation in its proposed concentration mill near here. Total cost, $60,000. T. E. Forester, 103 Miners Bank Bldg., Joplin, Supt.

Mo., Joplin—The Connor Investment Co., Miners Bank Bldg., is in the market for boilers for the heating system in the proposed hotel annex on 4th and Joplin Sts.

Mo., Joplin—The Klein and Stern Investment Co., Frisco Bldg., will build a concentration plant. New equipment including engines, boilers, etc., will be installed in same. Estimated cost, $35,000. A. Klein, Supt.

Mo., Joplin—The Miami Yellville Mining Co., West 7th St., will remodel its concentration plant and re-equip same Mashinery to be installed includes engines, boilers, etc. Total cost, $25,000. J. Taylor, Main St., Supt.

Mo., Joplin—The Muskogee Lead and Zinc Co. is in the market for conveyors, air compressors, etc., to installation in the proposed concentration mill near here. Total cost, $58,000. E. C. Beatty, Springfield, Supt.

Mo., Joplin—The Playter Bros. Mining and Realty Co., 315 Wall St., will build a concentration plant at the Silver Fox Mine near Monarch, Kan. Boilers, engines, belts, etc., will be installed in same. Total cost, $60,000. G. H. Playter, Mgr.

Mo., Richmond—The Missouri Gas and Electric Service Co. plans to enlarge or improve its plant here. J. H. Boggs, Engr.

Okla., Pilcher—The Southwest Missouri R.R., Webb City, plans to build an 18 mi. transmission line from here to Miami, in connection with the construction of a new electric railway. Estimated cost, $150,000. A. H. Rogers, Webb City, Pres.

Okla., Poteay—The Citizens Consolidated Power and Electric Co., recently incorporated, has petitioned the city for a franchise to install and operate an electric lighting plant.

Okla., Quapaw—The Miami Co. will build a concentration plant near here. Equipment including boilers, air compressors, etc., will be installed in same. Total cost, $250,000. J. P. McNaughton, 8 A St., S. E., Miami, Supt.

Colo., Brighton—The Town is in the market for new pumping machinery in connection with its proposed water work extensions. Total cost, $50,000. P. O'Brien, 306 American Bank and Trust Co., Denver, Engr.

Colo., Sterling—The Presbyterian Congregation will soon award the contract for the installation of a steam heating system in its proposed church. Wilson & Wilson, Commonwealth Bldg., Denver, Arch.

Wash., La Crosse—The Washington Water Power Co., Spokane, may take over the electric lighting plant here, and extend an electric transmission line from here to Endicott. C. E. Uhden, Spokane, Ch. Engr.

Cul., Tiburan—The Bureau of Yards and Docks, Navy Dept., Wash., D. C., plans to build a power house and a machine shop here. Estimated cost, $8000.

CONTRACTS AWARDED

Mass., Boston—The Board of Education has awarded the contract for the installation of a direct radiation system in the English and Latin High Schools on Warren Ave., to the J. L. Hern Engineering Co., 68 East St., $20,500. Noted May 28.

N. Y., Brooklyn—The Doehler Die Casting Co., 9th and Huntington St., has awarded the contract for the erection of a 7-story factory. A steam heating system and boilers for same, will be installed.

N. J., Kearney—(Arlington P. O.)—The Ford Motor Car Co., Highland Park, Detroit, Mich., has awarded the contract for the electrical work in connection with the proposed factory here, to the K. W. Electric Co., 49 Lawrence St.

Ky., Fulton—The Illinois Central R. R. 135 East 11th St., Chicago, has awarded the contract for the erection of various units including a 40 x 50 ft. boiler house here, to J. E. Nelson & Son, 118 North La Salle St., Chicago. Total cost, $225,000. The company is in the market for two 150 hp. boilers. Noted June 11.

Ohio, Columbus—G. Borden, Director of Public Service, has awarded the contract for the installation of a new heating system in the city hall, to the Huffman-Wolfe Co., Columbus. Estimated cost, $15,233. Noted May 14.

Ill., Amboy—The Illinois Central R. R., 135 East 11th St., Chicago, has awarded the contract for the erection of various units including a 40 x 150 ft. machine shop and boiler room, an 100 ft. electric turntable, etc., here, to W. J. Zitterell, Webster City, Ia. Total cost, $250,000. The company is in the market for two 150 hp. boilers. Noted June 11.

Ill., Carbondale—The Illinois Central R. R., 135 East 11th St., Chicago, has awarded the contract for the erection of various units including a 40 x 150 ft. boiler room and machine shop, an 85 ft. electric turntable, etc. here, to the Leyden & Ortseifen Co. 53 West Jackson St., Chicago. Total cost, $250,000 The company is in the market for two 150 hp. boilers. Noted June 11.

Ill., Mounds—The Illinois Central Ry., 135 East 11th St., has awarded the contract for the erection of a 40 x 50 ft. boiler house, an electric table, etc., in connection with the proposed improvement of terminal facilities here, to G. B. Swift & Co., 189 West Madison St., Chicago. Total cost, $250,000. The company is in the market for two 150 hp. boilers. Noted June 11.

Kan., Baxter Springs—The Board of Education has awarded the contract for the installation of fans and ventilation system in the Mark Twain and Eugene Field schools, to the M. C. Woodlong Heating and Ventilating Co., 512 Reliance Bldg. Kansas City, Mo. Estimated cost, $10,168. Plans include the installation of electric motors, fans, belts, wiring, electric switches and switchboards.

Mo., Kansas City—The Kansas City Railways, 303 Montgall St., has awarded the contract for the erection of a 43 x 82 ft. substation, to the L. Breitag and Son Constr. Co., 3701 West Prospect Pl. Estimated cost, $25,000. Noted May 14.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular Current	Individual Current
Buckwheat	$4.60	$7.10—7.35
Rice	4.10	6.65—6.90
Boiler	3.90	....—....
Barley	3.60	6.15—6.40

BITUMINOUS

Bituminous not on market.

Pocohontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.00 a year ago.

*All-rail to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* are as follows:

ANTHRACITE

	Circular Current	Individual Current
Pea	$4.90	$5.65
Buckwheat	4.85	5.60
Barley	3.80	4.00
Rice	4.25	4.80
Boiler	....	....

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Gross	Mine Price Net	Gross
Central Pennsylvania	$5.06	$3.05	$3.41
Maryland—			
Mine-run	4.84	2.85	3.19
Prepared	5.06	5.05	3.41
Screenings	4.50	2.55	2.85

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty, Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The ratte to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Current	One Yr. Ago	Current	One Yr. Ago
Pea	$3.45	$3.10	$4.70	$4.00
Barley	2.40	1.90	3.30	2.15
Buckwheat	3.40	2.90	4.40	3.80
Rice	2.90	2.40	3.80	3.40
Boiler	2.70	2.20	3.70	3.30

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes	$2.55—2.70	$3.25—3.40
Mine-run	2.35—2.50	3.00—3.15
Screenings	2.05—2.20	2.75—2.90

St. Louis—Prices per net ton f.o.b. mines are as follows:

	Williamson and Franklin Counties	Mt. Olive & Staunton	Standard
6-in. lump	$2.55-2.90	$2.55-2.70	$2.55-2.70
2-in. lump	2.55-2.90	2.55-2.70	2.55-2.70
Steam egg	....-....	....-....	2.20-2.40
Mine-run	....-....	2.35-2.50	2.00-2.20
No. 1 nut	2.55-2.90	2.55-2.70	....-....
2-in. screen	2.05-2.20	2.05-2.20	....-....
No. 5 washed	2.05-2.20	2.05-2.20	....-....

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump & Nut	Slack and Screenings
Big Seam	$2.05	$2.35	$1.75
Pratt, Jagger	2.25	2.55	1.95
Corona	2.30	2.65	1.95
Black Creek, Cahaba	2.75	3.00	2.35

Government figures.

Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.
